3. Jobs showing an excessive expenditure of manhours or elapsed maintenance time can be immediately identified and corrective action can be instituted.
4. Conditions affecting the productivity of the work center, lack of parts, tools, etc., can be recognized and brought to the attention of management.

Monthly Production Report (MDR 2)

This report is a summation, by work center, of all maintenance action, support action, and technical directive compliance forms submitted during the month. This report assists the work center supervisor in obtaining maximum utilization of the direct labor available to his work center. The total production manhours expended on maintenance and support actions and technical directive compliance can be compared to the available direct labor manhours to determine if a significant imbalance exists. This report further provides ways of comparing the productivity of the work center to set or desired standards to insure that an adequate outlay of work is being realized.

Job Control Number Consolidation Report (MDR 3)

This report is a consolidated listing, by organization, of all maintenance actions and

14289

technical directive compliance actions submitted during the month by the parent organization, as well as those submitted by the supporting activity. Support actions are not included in this report. Only those actions which involve maintenance of equipment, component repair, and technical directive compliance are listed.

It is designed for the maintenance officer, in order that he might have at his disposal a comprehensive record of maintenance accomplished on items for which he is responsible. The type equipment and component worked on, maintenance actions performed, description of the malfunction, manhours utilized, failed parts involved, repair activity, date the job was originated, and the date of job completion can be identified to each job control number issued by the organization. This report provides the maintenance officer with a brief summary of who did what for whom, and when it was accomplished.

Intermediate level maintenance performed on components removed from an organization's aircraft, support equipment, etc., is included in this report. This information can be used to determine the defect found in the removed component, the extent of work required to repair the defect, and similar statistics. Additionally, items removed without ample cause can be isolated. Further research may reveal poor troubleshooting techniques, inadequate test equipment, etc.

The MDR 3 is an optional report and it is not prepared by data services unless specifically requested by an activity.

Technical Directive Compliance
Reports (MDR 4, Parts 1 & 2)

These reports provide a detailed listing, by organization, of TDCF's submitted during the month. They are designed for maintenance control managers as an aid in scheduling and maintaining a positive control of technical directives. Parts 1 and 2 of MDR 4 contain identical information; however, they are sorted, tabulated, and totaled differently in order to provide a wider range of useful information.

Typical uses of these reports by maintenance control managers are as follows:

1. Serve as a running account of technical directives complied with by TDC identification, or by individual bureau or serial number in order to maintain a smooth running program.

2. Identification of total manhours utilized in each TDC or in all TDC's combined.

3. Identification of TDC's which did not apply or which had been previously incorporated.

4. Serve as a record of all work centers that worked toward each technical directive compliance whether they were assisting, or had prime responsibility.

The MDR 4, Part 1 is an optional report and it is not prepared by data services unless specifically requested by an activity.

System and Component
Maintenance Report (MDR 5)

This report is a detailed listing of all MAF's and summation of SAF's submitted by each action organization during the month. It is designed to provide maintenance managers a listing of items repaired on equipment, items removed, installed, or replaced, and items processed through maintenance shops. It allows identification of total manhours utilized for each type of support maintenance in order to determine the average time spent on preflight inspection, mission configuration, etc.

Checks can be made of high manhour consumers by systems, or by components within systems, to determine what systems or components caused the most problems. Further investigation may reveal that the inspection of the system is not effective, or, if the same components continue showing up as a discrepancy, perhaps correspondence should be initiated recommending changes to manufacturer's specifications. Selections of repeat failure items can be made with the possibility of establishing the cause of the failure.

When Malfunction Was
Discovered Report (MDR 6)

This report is intended for the maintenance officer and contains data extracted from MAF's. It is used to determine the number of aborts caused by mechanical failure and their causes. It further identifies the number of items processed and manhours expended as a result of discrepancies discovered during acceptance checks on recently assigned aircraft. Additional data is also provided for the identification of the number of malfunctions discovered during quality assurance inspections and during functional test flights.

Maintenance Actions by
Individual Item Report (MDR 7)

This report contains a line entry for each MAF that was submitted during the month on an item of equipment that can be identified by a bureau or serial number. It is intended for the maintenance officer.

Typical uses of the report by the maintenance officer are as follows:

1. Identification of the cost, in manhours, to support a single aircraft.
2. Identification of the cost, in manhours, to support a single system within an aircraft, and identification of the system that caused the most trouble.
3. Identification of the cost, in manhours, of scheduled or unscheduled maintenance performed on the aircraft.

Beyond Capability of
Maintenance and Repair
Data Report (MDR 8,
Parts 1, 2, 3, & 4)

This report is a tabulation of all items processed through an Intermediate level maintenance activity on the No. 3 copy of the multicopy MAF during the month. To facilitate the extraction of information, the report is prepared in four parts. The difference between parts 1, 2, and 3 is the manner in which the data is sequenced or summarized, while part 4 utilizes a different sequence and data source. The report is intended for maintenance managers at the Intermediate level.

The basic design of this report lends itself to determining percentages of items not repaired, items received that require no repair, and items that were repaired. Typical uses of the report by IMA maintenance managers are as follows:

1. Determination of the percent of the total components processed in an IMA that are not repaired.
2. Determination of the percent of the components received in an IMA that do not require any repair.
3. Determination of the percent of the component received in an IMA that are returned to the Supply Support Center in an RFI condition.
4. Identification of a squadron responsible for a high number of processed components that do not require any repair.
5. Determination of the percent of items not repaired that were not repaired because of a lack of spare parts.
6. Determination of the repair capability of individual work centers.
7. Determine the total manhours and elapsed maintenance time expended in the repair of an item by a work unit code.

The MDR 8, Part 1 is an optional report and it is not prepared by data services unless specifically requested by an activity.

Failed Parts Report (MDR 9)

This report is a detailed listing, by organization, of all failed part cards punched from MAF's submitted during the month. It is intended for the maintenance officer. Quality assurance personnel can use the report as a lead-in to parts reliability studies. This report is also used by material control personnel to determine parts usage rates.

Repair Cycle Data
Report (MDR 10)

This monthly report is a detailed listing, by organization, showing the number of days involved in the turn-around time, and the elements that compose the turn-around time, for each reparable component processed through the IMA as documented on the No. 3 copy of a MAF. Typical uses of the report by maintenance managers are as follows:

1. Analysis of elements composing the turn-around time for reparable components.
2. Determination of job standards.
3. Identification of delays encountered in the repair cycle with resulting indications of initial areas to be investigated in order to reduce processing and repair delays.
4. Identification, by component serial number, of components that appear repeatedly in the Intermediate maintenance activity repair cycle.

No Defect Report (MDR 11)

This report is designed for maintenance managers at the Intermediate level. It provides a means to rapidly and accurately identify the areas in which the Intermediate activity is expending effort on components which need no repair. Naturally, actions of this type seriously impair the ability of an Intermediate activity to take rapid action on actual repairs.

14291

Secret

This report provides for the identification of Organizational activities which may have troubleshooting difficulties. It also identifies components which require improvement or for which additional Organizational level test equipment is necessary.

SPECIAL REPORTS

Maintenance managers and analysis personnel have at their disposal an extremely valuable tool in the form of special reports. Many times in the past, an area that should have been studied was avoided because of the difficulty of extracting data from available reports and forms. If the information is known to exist in MDR files, it can be obtained in a special report. Special reports should not be used indiscriminately because of the additional, and often excessive, workload imposed on data services personnel and machines. However, if there is justification, these reports can be readily obtained.

Special reports may be provided on a one-time or recurring basis. Any, or all, standard MDR's may be prepared as special reports upon demand. This occasion could arise from a desire to produce certain reports for a specific period other than the normal reporting period. Standard reports may also be prepared as special reports for maintenance data generated away from home, if an organization spends part of the reporting period away from home and there is a need to reflect these data separately from the total data.

In designing a special report, there are two prime factors which must be considered—the intelligent selection of the applicable data and a method of sorting the punch cards to select those containing the desired information, and the design of the format in which the report is to be printed. It should be remembered that the wiring of a control panel for an EAM is difficult; therefore, whenever possible, the use of a control panel that is used in standard reports preparation should be considered.

The content, or subject matter, of special reports depends upon the needs of the requesting activity. Some activities may use several special reports, whereas others may use none. The special reports discussed in the following sections represent a few typical applications.

Configuration by Individual Item Report (MDR S-1)

This type of special report is prepared from information extracted from the configuration control form. The frequency of the report is dictated by the volume of forms processed, a timely need for the information concerned, and similar criteria. A special report of this type could be used by the log yeoman, or other maintenance personnel involved in changes of equipment configuration, and could be used to monitor changes, verify records, etc.

No Defect Report (MDR S-2)

This type of report may be requested by activities that need additional summarized data on the effort and time expended on maintenance actions in which there were no apparent malfunctions. Some of the types of data required for a report of this nature are as follows:

1. Reported malfunctions which were either nonexistent or could not be duplicated.
2. Manhours used in cannibalization.
3. Manhours expended in removing and installing items with no known malfunction, solely to facilitate other maintenance.
4. Those items removed or installed because of time change or scheduled maintenance.
5. Those items removed and installed because of technical directive compliance.
6. Those items removed as part of a matched set.

After the selection of desired data has been extracted and summarized in report form, it can be readily analyzed and used for conclusions with regard to questions posed by management.

Foreign Object Damage Report (MDR S-3)

A report of this type could be used to measure the maintenance effort attributable to foreign object damage. Components replaced, repaired, condemned, etc., can be identified by means of data contained in the MDR files. Indirectly, a report of this type would reflect current housekeeping conditions (cleanliness of ramps, runways, hangar areas) or the maintenance proficiency of the personnel (adherence to proper maintenance practices). The source of data for this report would be extracted from MAF's which contain malfunction description codes showing foreign object damage.

14292

14291

Corrosion Control/Treatment Report (MDR S-4)

This special report provides a possible means of monitoring a corrosion control program or investigating the amount of corrective corrosion treatment necessary in an organization. The information for this report is extracted from SAF's and MAF's which are documented showing corrosion control or corrosion treatment actions.

Study of a report of this type would show if any type aircraft required more treatment than others. A check on where these aircraft had been operating might lead to better corrosion control programs for aircraft where special operations or deployment is involved. It would be a simple matter to determine if any specific portion of the aircraft needs a better corrosion control program because of its design or location.

The typical special reports discussed in the preceding paragraphs point out the variety of specialized information that can be provided from the maintenance data reporting system. Carefully selected data, properly displayed, is of utmost assistance to conscientious maintenance managers.

MAINTENANCE DATA ANALYSIS

The MDCS was designed to accumulate factual data pertaining to all phases of aircraft maintenance. As previously discussed, this data is made available to maintenance managers in the form of standard and special reports. The progressive maintenance manager can identify the potential of these reports and successfully use them in the course of managing his particular work center or maintenance activity.

The function of analysis is to examine the data contained in the reports and determine what impact the conditions indicated have on the maintenance effort. Analysis brings to light both good and bad conditions. Maintenance managers should be informed not only of unfavorable conditions in a maintenance activity, but also of those conditions that appear to be favorable. Obviously, the MDCS will be of little value to maintenance managers if its principal characteristic, the ability to furnish data for analysis, is not utilized to the fullest extent. AZ's must exert every effort in the fields of data collection and data analysis to insure that management has the required information. Senior AZ's performing management functions should use the results of analysis in a constructive manner.

It is evident that the time, trouble, and expense involved in collecting and machine processing maintenance data cannot be afforded if the data is not continuously and constructively used by maintenance managers. In order for it to be used, it must first be analyzed. In effect, the processes of data collection and machine processing provide a mass record of what happened. The process of data analysis sorts out from this mass of data significant events which require corrective action or otherwise merit management attention. By this process, managers are provided with filtered facts as a basis for decision.

The depth and amount of analysis performed on collected data vary from one activity to another, dependent upon the mission assigned, special circumstances involved, etc. AZ's performing analysis functions should strive for continual refinement of the data analysis process in order to realize full benefits from the system and also for system improvement.

ANALYSIS DIVISION

The Aviation 3-M System has brought about major changes in the field of data analysis at Organizational and Intermediate level maintenance activities. Numerous reports are analyzed for the purpose of furnishing management factual information. This task is properly the function of the analysis division.

An analysis division has been established in each Organizational and Intermediate maintenance activity. In regard to size, this is probably the smallest division in a maintenance department; however, this is not in keeping with its importance. This division is charged with the responsibility of insuring that the maintenance data collection system is operated in an orderly and efficient manner, and monitoring and controlling the system for the maintenance department. It also serves as the contact point between the activity and data services and coordinates, with data services, the day-to-day system operation.

In regard to organizational structure, the analysis division is located directly under, and operates as a staff division to, the Aircraft Maintenance Officer. This division is responsible for the smooth and correct operation of the 3-M System at Organizational and

14293

Intermediate level maintenance activities and provides assistance and guidance as needed to achieve this end.

Specific tasks performed by the analysis division for the overall system include the following:

1. Coordinate the expansion of work center and labor codes within the code structure provided in governing instructions.

2. The designation of pickup and delivery points for source documents and machine reports.

3. Coordinate with data services for delivery, pickup, and processing procedures between the maintenance and data services activities.

4. Insure that an adequate supply of necessary manuals, source documents, registers, etc., are available in the various work centers.

5. Coordinate training schedules to insure that all maintenance personnel receive adequate training on the system.

6. Assist work center supervisors by providing on-the-job training as required.

The analysis division has numerous responsibilities and performs various functions in addition to those previously mentioned. Some of these are discussed in the following paragraphs:

In the area of manhour accounting, the analysis division performs the following functions and tasks:

1. Monitors manhour accounting throughout the maintenance organization.

2. Advises maintenance officers of all areas of weakness in the use of the manhour accounting system. Training in manhour accounting is provided through actual demonstration, classroom instruction, or on-the-job training as appropriate.

3. Accomplishes specific analysis of manhour accounting data as necessary.

4. Assists maintenance supervisors in analyzing manhour reports.

5. Coordinates all manhour accounting matters with data services, including the preparation of additional required reports.

6. Monitors the assignment of personnel to work center XXO. This includes the responsibility for submission of applicable newly assigned and transferred cards and for maintenance of the master roster for this work center. NOTE: Work center XXO consists of those aviation maintenance personnel assigned to a maintenance activity that are working in functions outside maintenance. For example, personnel assigned to mess cooking, compartment cleaning, shore patrol, special services, etc., are assigned to this work center.

7. Promulgates listings of work center codes and sublabor codes that are used locally.

The analysis division closely monitors the maintenance of all master roster listings to insure that all permanently assigned and transferred transactions, permanent changes in assigned labor code, and revisions which occurred during the reporting period have been entered. At the end of each reporting period, work center master roster listings are reconciled against the copy maintained by the analysis division, which is updated daily utilizing the assigned, transferred, and revision manhour accounting cards submitted by the work center supervisors. Any differences are resolved with the assistance of applicable work center supervisors.

Upon completion of this reconciliation by the analysis division, the original copies of the master roster listings, amended as necessary, are forwarded to data services for processing. At this time, the analysis division advises data services of the number of original assigned manhours per man in the forthcoming period.

The analysis division is the hub around which an activity's maintenance data reporting system revolves. This division receives all the source documents from all work centers, reviews them for completeness and accuracy, and insures that they are delivered to data services. The analysis division must also review and analyze the resulting reports for information that is of benefit to the maintenance activity. Some of the responsibilities that are assigned to the analysis division in the area of maintenance data reporting are as follows:

1. Sort and arrange all source documents prior to their delivery to data services for keypunching.

2. Monitor the maintenance data reporting system.

3. Collect and maintain in narrative, tabular, chart, or graph form the data needed to monitor, plan, schedule, and control the maintenance effort.

4. Analyze and compare maintenance performance against maintenance plans and workload estimates.

5. Review maintenance data reports for significant variations from normal. Isolate and identify the trouble areas revealed by these reports for further investigation by the maintenance officer and other appropriate supervisors.

14294

6. Develop methods, in coordination with data services, for extracting selected data from the maintenance data reporting card decks for use in making detailed analyses of particular problem areas.

7. Assist the maintenance officer and other supervisory personnel in developing new types of recurring machine run reports deemed necessary for management of the maintenance effort.

8. Prepare briefs and explanations covering the content of the reports produced by the MDRS. These briefs are presented to the commanding officer, the maintenance officer, and other supervisors as required or requested.

9. Identify and analyze material deficiencies and high manhour consumption areas, and study other pertinent trends.

10. Assist the training section in identifying areas of possible deficiencies in training.

11. Assist the material control work center in relating the contents of monthly maintenance data reports to material consumption and forecasts for material.

12. Train work center personnel in proper documenting procedures, and assist supervisory personnel in the correct interpretation of resulting reports.

13. Assist in the preparation of pertinent reports.

14. Coordinate all data collection matters with data services, including the preparation of additional reports as required.

The responsibilities of the analysis division concerning aircraft and support equipment statistical data are closely related to those previously discussed. In addition to the analysis functions performed on collected data, personnel of the analysis division screen submitted ESD and AMSE cards for accuracy and completeness, distribute both aircraft and support equipment statistical data reports, and assist in the reconciliation of errors.

In summary, the analysis division is the element in aviation maintenance activities in which all data generated from the maintenance organization are collected, broken down, studied, and evaluated. The analyst performs these functions in order to predict future trends, identify potential trouble areas, establish performance standards, develop capabilities, and evaluate the results of statistical studies.

Thus the prime responsibility of the analyst is to insure that management has up-to-date information relative to all areas of the organization at all times. In addition, analysts may be required to assist maintenance supervisors by explanations or interpretations of maintenance reports and summaries. Therefore, the duties of an analyst consist of (1) analyzing maintenance data to compare performance against plans, schedules, and workload estimates, (2) reviewing reports to identify production effectiveness trends and areas requiring management action, and (3) assisting maintenance activities and personnel in the operation, interpretation, and use of maintenance, manhour, aircraft, and support equipment data.

Document Control Form

The Document Control Form (fig. 5-2) is used to control the flow of source documents between the originating activity and data services. Daily, at a specified time, all completed source documents held in the work centers are delivered to the analysis division. The analysis division is responsible for the grouping of documents by type and for the preparation of the Document Control Form.

To maintain an even keypunch workload, it is necessary that all source documents be delivered for keypunching at least once each working day. Two copies of the Document Control Form are prepared each time source documents are submitted to data services. The various source documents are separated, grouped, and counted to aid the data services keypunch operation. The analysis division enters under 1st COUNT the number of documents in each category submitted. Data services verifies this number by entering their count in 2nd COUNT. After the daily process has been completed by data services, the original copy of the form is filed and the carbon copy is returned to the analysis division for filing. The filed copies are maintained for a minimum period of 3 months.

If a particular activity desires to identify the data generated in an away from home situation, a one-character code is entered by the analysis division in the space titled AWAY FROM HOME CODE. Any numerical or alphabetical character desired by the maintenance activity is entered in this space; for example, "F" for USS FORRESTAL, "C" for NAS CECIL FIELD, etc. All source documents submitted with an away from home code on the Document Control Form are processed to include this code in the machine records produced. This control feature can be utilized to produce special reports upon request.

14296

If, during the keypunch operation at data services, a document is found to be incomplete, in error, or illegible, it is returned to the originating activity for completion or correction. The questionable data is encircled in red by data services. A total of the rejected forms is entered in the appropriate column of the Document Control Form by data services. Rejected documents are corrected and returned to data services with the documents submitted the following working day. Resubmitted documents are totaled with the regular documents on the Document Control Form.

Rejected documents or late documents that are submitted after the end of a reporting period require submission with a special Document Control Form if the data is to be included with the previous month's data. Any such submission requires special coordination with data services.

The ENTRY PROCESS column is completed by data services and represents the total number of punch cards keypunched from each group. The CONTROL columns, A and B, are provided for additional local controls if desired.

Calculating Machines

Senior AZ's performing analysis functions in Organizational and Intermediate level maintenance activities work with large quantities of numbers. Naturally, speed and accuracy are of utmost importance. To simplify many of the required figuring processes, calculators are used. Calculating machines are similar in appearance to adding machines; however, they can perform many additional functions.

Because of the nature of work which a calculator performs, it is a very delicate and intricate machine. Extreme care should be observed when lifting or moving calculators from one place to another. Many precision made parts and mechanisms are required for the accomplishment of its many functions. When the operator of a calculator depresses bars or keys on the keyboard, he sets in motion specific links, levers, bellcranks, cams, etc., for accomplishing a specific function.

Most calculating machines do not use tape for printing desired information. Instead, figures are displayed in small windows or dials. Calculators add, subtract, multiply, divide, and extract square roots. Operation of all types is based upon the principle that all calculations consist of addition, either positive or negative. In other words, multiplication is simply repeated addition, while division is repeated subtraction, or negative addition.

There are several makes and model of calculators used in the Navy. Some of these include those manufactured by Monroe, Remington, Friden, and Burroughs. These machines, although different in some respects, have many similar keys, mechanisms, and parts, because the operations they perform are closely related.

Discussion of the operation of all the various types of calculators that are used in analysis work is not appropirate in this training course. The information provided here is general in nature, and the machine discussed is a representative type of those used in analysis functions.

The Monroe model 8F-213 calculator (fig. 5-3) is one type used by aircraft maintenance activities in performing analysis functions. This particular model is equipped with an automatic decimal system. By setting certain movable decimal markers, located below each column of numbers, and placing required controls in their normal positions, the operator can work problems with decimal numbers and they are pointed off automatically.

In order to better understand operation of this machine, the use of certain locks, dials, and controls is discussed in the following paragraphs. These locks and controls position the carraige automatically, control the entry of figures into a set of dials, and produce selective clearance.

This machine has three dial locks which are located on the left end of the carriage. The uppermost lock, when down, prevents clearing of upper right dials. The normal operating position of this lock is in the UP position. The left and right lower dial locks are below the upper dial lock, and these locks control certain functions of the lower dials. The left lower dial lock, when down, prevents clearing lower dials from 10 to 21. When down, the right lower dial lock prevents clearing lower dials from 1 to 9. The normal operating position for both of these locks is in the UP position.

There are eight tab stops located on the carriage above the right upper dials. These stops, when depressed, stop the carriage in the desired position in multiplication and division.

The two carriage shift keys, located on the right upper part of the keyboard, are used to shift the carriage. These keys are readily identifiable by an arrowhead, one pointing to the left and the other to the right.

14297

AZ. 15

Figure 5-3.—Monroe model 8F-213 calculator.

This particular model has four different dials, all located on the carriage. The upper dials are divided into two sets, right and left. The right upper registers the multiplier and the quotient and is used in cumulative multiplication. The left upper shows multipliers in black and quotients in red. The lower dials, located directly below the upper sets, register the sum in addition, the remainder in subtraction, and the product in multiplication. They also register the dividend before starting division. The multiplier dials, located below the lower dials, register the multiplier.

The enter multiplier key, identified by X, is located on the keyboard directly below the carriage shift keys and transfers amount set on keyboard to be used as multiplier to multiplier dials.

A constant multiplier lock, located on the right end of the carriage, provides for use of the same multiplier constantly with different multiplicands. The normal operating position for this lock is UP.

The dividend alignment lever, located on the lower left side of the keyboard, controls alignment of the carriage for lining up dividend in

1427

lower dials with divisor on keyboard. The normal operating position for this lever is UP.

The automatic keyboard clear control is a two-position control located below the keyboard in the center of the machine. Amounts on the keyboard clear automatically after division or multiplication processes when this control is in the LEFT position. When in the RIGHT position, this control retains the amounts on the keyboard after division or multiplication. The normal operating position is LEFT.

The upper dials control lever, located on the right side of the keyboard below the plus bar, is a three-position control. In the UP or + position, positive amounts are entered on the upper right dials. In the DOWN or - position, negative amounts are entered. In the CENTER or 0 position, all entries except quotients are eliminated from the upper right dials.

The repeat-nonrepeat lever, located to the left of the upper dials control lever, is a two-position control. With this control in the NONREPEAT position, the keyboard is cleared after depressing the plus or minus bar. In the REPEAT position, the amount remains on the keyboard after depressing the plus or minus bar. The normal operating position for this lever is in the DOWN or NONREPEAT position.

The transfer slide, located directly above the multiplier dials, controls the automatic positioning of the carriage. A pullout type knob releases the slide so it can be moved from one numbered position to another.

The three clear keys, located on the lower right side of the keyboard, provide a means of individually clearing the upper and lower dials and the keyboard. The key marked with a U, when depressed, clears the upper dials. Likewise, the L key clears the lower dials and the C key clears the keyboard.

By depressing the stop key, located on the lower left side of the keyboard and identified by an S, all multiplication and division processes are stopped.

The enter dividend key is located directly above the upper and lower dial clear keys. This key is identified by ←÷; and when dpressed, automatically clears the upper and lower dials, shifts the carriage to the right, and clears the keyboard.

Prior to using the calculator for a specific function, it should be checked to insure that the dials are clear and the controls are in the normal operating position. After this has been accomplished, the operation of the machine in performing arithmetic problems is a relatively simple process. The major requirements is the knowledge of basic arithmetic symbols.

For addition, the number or group of numbers to be added is set on the keyboard one at a time. After each number or group is set, the plus bar, located on the keyboard adjacent to the carriage shift keys, is depressed. Each time the plus bar is depressed, the sum is registered in the lower dials.

In subtraction, the minuend is set on the machine and the plus bar is depressed. The subtrahand is set and the minus bar, located on the right side of the keyboard above the plus bar, is depressed. The remainder is registered in the lower dials.

A combination of addition and subtraction is accomplished by setting the numbers to be added and depressing the plus bar after each number or group of numbers. The numbers to be subtracted are set and the minus bar is depressed. The remainder is registered in the lower dials.

There are several multiplication processes that can be performed with this particular model. These include simple multiplication, accumulative multiplication, negative multiplication, multifactor multiplication, and constant multiplication. For the sake of brevity, only the simple multiplication process is explained. Some of the other processes require the use of additional keys located on the bottom row of the keyboard and other keys previously discussed.

For simple multiplication, the multiplicand is set and the enter multiplier key is depressed. The multiplier is set and the multiply key, located to the left of the keyboard clear key, is depressed. The product is registered in the lower dials.

Division is performed by setting the dividend and depressing the enter dividend key. Next, the divisor is entered and the divide key, located on the bottom row of the keyboard to the right of the stop key, is d ressed. This registers the quotient in the upper dials.

In addition and subtraction, the calculator must be manually cleared after each operation; however, in multiplication and division this is not required because the machine clears automatically.

Although calculators perform many more functions than are discussed here, most stem from these basic operations. With proper training and the aid of the manufacturer's technical manual for a particular model, senior AZ's should have little difficulty in the operation of calculators.

ANALYSIS TECHNIQUES

As has been pointed out previously, the various MDCS reports contain a wealth of valuable information. This information consists of coded elements of data listed or summarized in logical arrangements. To be of practical use to management, selected data elements must be assembled, studied, and suitably presented. The accomplishment of these functions is maintenance data analysis.

One major requirement for the accomplishment of a comprehensive analysis is a thorough knowledge of the contents of each MDCS report and an understanding of basic analysis principles or techniques. These analysis techniques encompass the extraction, examination, and presentation of pertinent data. The resulting analysis products, properly used, assist management in attaining effective and economical utilization of personnel and material resources.

Certain standards have been established which provide all Navy maintenance activities with a "yardstick for measurement" in the maintenance and readiness fields. These include job standards (standard numbers of manhours to perform certain repair or maintenance jobs), readiness standards for various models of aircraft, and overall maintenance personnel utilization standards. For example, a 45-45-10 formula may be used as a standard for maintenance personnel utilization. Of the total manhours available to a maintenance organization over a given period of time, it is expected that 45 percent of them will be expended performing direct maintenance labor; 45 percent in indirect maintenance labor such as supervision, administration, quality inspection, and material control; and the remaining 10 percent going to nonproductive labor such as training, leave, medical, and disciplinary lost time.

When the direct labor portion drops below 45 percent, the indirect labor exceeds 45 percent, or the nonproductive time exceeds 10 percent, the normal expected standards have not been met, and possible corrective action may be required. Detailed analysis of collected data is required in order to determine which standards were met, which were not met, and any requirements for corrective action.

Analysis Requirements

The requirements for analysis may stem from various sources and apply to a wide range of maintenance problems. In most cases, analyses are initiated and performed in order to find answers to specific problems. However, in other situations, analyses of selected areas of maintenance are completed as monitoring actions. In any case, the requirements for analysis should be the result of a need to know situation imposed by management.

In order for any analysis to be effective, it is important that the problems or areas to be analyzed are adequately defined. Senior AZ's performing analyses should clearly understand what information management desires prior to starting the analysis. Next, the data to be analyzed should be carefully selected, analyzed, and presented to management in an understandable format. An analysis which is based on clear, concise requirements and is presented in an easily understood format is more likely to be meaningful and useful to maintenance managers than one based on generalities. The AZ analyst should make known, to management, what information is available through analysis of the various MDCS reports.

Data Selection

Once the subject of the analysis is known, the analyst must determine what data is needed to fulfill the requirement. There are no standard rules that can be applied to this phase of analysis. The training and experience of the analyst, in conjunction with his knowledge of the data actually available in the MDCS reports, have great influence on the selection of correct data. Selected data must be chosen wisely, insuring that all facts having a bearing on the subject will be included in the analysis. It is at this point that the analyst's knowledge of the contents of each MDCS report pays off. He must know which report, or combination of reports, best provides the data he intends to use.

Although all the MDCS reports are of prime importance to all AZ's, it is imperative that senior AZ's performing analysis functions have a thorough knowledge of the data contained in the various standard and special MDCS reports.

Data Extraction

The extraction of data is normally accomplished by a mechanical process. However, certain columns or lines of the various MDCS reports must be carefully screened to identify the desired data. After selection, the data is usually

DESPI
14200

transposed to some type of worksheet to facilitate subsequent steps. The design of the worksheet should be simple, allowing ample space for the posting of extracted data in systematic sequence, and providing space for computation of totals and subtotals as needed. Analysts should design worksheets to meet the needs of the particular activity to which they are assigned.

Data Translation

The major portion of extracted data, in its pure form, consists of coded entries. In most cases, this coded data must be translated or changed into an understandable, written description before being used in analysis. Few maintenance personnel are able to sight read and completely understand a series of coded entries. For this reason, much of the coded data must be translated into an understandable, written description. Frequently, the design of worksheets will incorporate translation provisions. For example, columnar headings may contain both the coded and descriptive terminology.

Data Examination

This is the critical stage of analysis, as it involves the detailed study or examination of accumulated data. The extent and the quality of the examination are limited only by the skill, resourcefulness, and imagination of the analyst performing the analysis. In this respect, there are no restrictions as to who may accomplish an analysis. In many instances it is desirable that an analysis be completed in its entirety by personnel technically qualified in the subject being analyzed; however, this is not always possible. Identical results are often obtained through the use of teamwork. For example, personnel assigned to the analysis division may accumulate the required data, call in quality assurance representatives to examine the data, and jointly prepare a commentary pertinent to the analysis. Likewise, quality assurance may accomplish many phases of the analysis, calling on the analysis division only for assistance in the selection and extraction of the desired data.

Regardless of who accomplishes the examination, the intent of the detailed study of accumulated data is (1) to determine if a problem actually exists, (2) to identify factors contributing to the problem, (3) to list possible conclusions, and (4) to suggest possible alternative courses of action.

During this phase of analysis, certain standards, statistical formulas, and other measuring criteria are used. It should be remembered that any decisions or actions based on the detailed study are the responsibility of management, not the analyst.

ANALYSIS PRODUCTS

As has been previously stated, the results of analyses must be presented in such a manner as to be readily understandable by intended users. Various displays in the form of charts, graphs, and tables are used for this purpose in maintenance data analysis. To be effective, these presentations should be designed to meet the needs of intended users. The old saying "a picture is worth ten thousand words" is especially true when applied to analysis products. By use of graphic presentations, a word picture can be made to convey a meaning to others that may otherwise be difficult to understand.

Presentation is as much a part of the job as is data collection and analysis. Effective presentation requires a good deal of imagination and ingenuity on the part of the analyst. The long, tedious hours spent collecting, studying, and analyzing maintenance data may end up being presented orally, narratively, or only as a curved line or several crosshatched bars on a graph.

The way presentations are constructed or designed and the manner in which they are presented may determine the success of failure of the entire study. All conclusions must be interesting, concise, and easily understood, and at the same time be eye appealing and clever enough to hold attention of those managers or other persons for whom the presentation is being made.

In order to acquaint AZ's with some of the many ways of presenting analysis products, the following general information on graphic presentations is provided. While studying the following paragraphs, keep in mind that a graph is a method of presenting statistical data in visual form.

For the sake of simplicity, graphic presentations may be divided into two classes—analysis charts or graphs made for the use of the analyst, and presentation charts and graphs used to present information to other people.

14301

A bar chart is a visual contrast between quantities by comparison of bars of varying length and uniform width, arranged vertically or horizontally. Two types of bar charts are absolute charts and percent charts. When constructing this type of chart, remember that a bar should be neither short and wide nor long and narrow. Also, if space permits, bars should be separated by spaces about one-half the width of the bar. A scale is generally useful, and guidelines are helpful in reading this type of chart.

A pie chart or diagram is a chart of circular shape broken into subdivisions. The size of the sections indicates the proportion of the component part to the whole. Since this type of chart is in a circle, 1 percent equals 3.6 degrees; and this fact is important when constructing a pie chart depicting percentages.

Sectors should be arranged clockwise according to size, and a uniform arrangement of sectors must be made in comparing charts. A minimum of sectors should be used in pie charts. Whenever possible, wording and percentages should be placed horizontally in each sector. Sometimes the effectiveness of a pie chart is intensified by shading, crosshatching, or using different colors for the various sectors. However, if this is done in place of wording in each sector, a legend should be provided to indicate their meaning. A pie chart is difficult to construct accurately, and it is difficult to estimate visually with any degree of accuracy the proportionate size of the sectors when percentages are not indicated.

Line or curve graphs show variations in data by means of a line or curve. They are used to picture a time series (show a trend) and for showing frequency distributions. These graphs are normally constructed on commercially prepared graph paper or a locally prepared substitute. When constructing these graphs, the starting point is selected where a vertical and a horizontal line meet. This is the 0 point. The vertical line from this point is the Y axis or scale and the horizontal line the X axis or scale. These graphs are constructed by plotting points whose positions are determined by their respective values on the X and Y scales and connecting these points with lines.

There are many kinds of special charts, a few of which are mentioned to give an idea of the possibilities for graphic presentations.

Silhouette charts may be constructed to show positive and negative deviations from a base line filled in.

Component part (band) charts show variation in the component parts as well as the total.

High-low (range) charts may be used to show a range of variation over a period of time.

Regardless of the type of graphic presentation used, there are numerous rules to be considered in their preparation. These include, but are not limited to, the following:

1. Plan in advance of the construction.
2. Keep the presentation simple, honest, and accurate.
3. Try not to create the wrong impression.
4. Use one subject at a time.
5. Keep background clear of unnecessary grids. Grid lines should be drawn very lightly and marginal lines slightly heavier than other grid lines.
6. Do not crowd the material.
7. Title fully and accurately. It should be placed at the top center of the graph and should include nature of data and period covered.
8. Start scales at zero and place scale values along X and Y axes.
9. Be neat and prepare an attractive presentation.
10. Include pertinent comments on charts, graphs, and tables. A presentation worth making is worthy of comment.
11. Use short, complete notes when necessary. Footnotes should be placed under the graph.
12. Indicate the source of the data contained in the presentation under the graph.
13. Place all lettering horizontally, if possible.
14. The presentation should be large enough to be seen by all who need to see it. However, chart proportions should not give misleading impressions.

In the following sections some of the many analysis products that can be derived from MDCS reports are discussed. These are but a few of the many analysis applications, examination methods, and analysis techniques found in maintenance data analysis. The information provided is general in nature and in no way is intended to prescribe standard reporting formats. The illustrations should be studied along with the text in order to more fully understand maintenance data analysis products.

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

MANAGEMENT EVALUATION CHARTS

Analysts construct this type of chart to portray the distribution of manhour assets, by labor category, within a particular activity. The primary objective of this type of chart is to assist in the process of internal management by illustrating the relationship that exists between manhour assets and their actual use. Management evaluation charts may be constructed for individual work centers, branches, or the whole maintenance activity. A work center management evaluation chart is depicted in figure 5-4. This is a simplified version; however, a chart of this type could be modified to include the amount of overtime within individual labor categories or to show productive manhours for selected types of equipment.

As shown in figure 5-4, the source of data for this type chart is MHA 2 and MDR 2. The TOTAL MANHOUR ASSETS column includes the sum of net assigned and gross overtime manhours less overtime reported in absence labor codes (810 through 950). These total assets are divided into the various labor codes in which the manhours were expended. These include direct, indirect, nonproductive, duty absence, and nonduty absence labor codes.

The column titled OVERTIME contains all overtime manhours reported in labor codes 500 through 740. The last column contains the total number of manhours expended by the work center that were documented on maintenance action, support action, and technical directive compliance forms. The percentage shown in this column represents the reporting effectiveness of the work center and is obtained by dividing the manhours entered in this column by the manhours entered in the DIRECT column. The other percentages are obtained by dividing the manhours listed in each labor category by the manhours entered in the TOTAL ASSETS column.

The available direct labor (labor code 500) manhours, shown as 58.3 percent of the total

MANAGEMENT EVALUATION CHART ACTIVITY: VF-14 WORK CENTER: 210 PERIOD: 1 through 30 June 1968

14303 POCAI

206

assets in figure 5-4, is a highly variable item. Much depends on the type of work center involved. The maintenance control work center would probably have no entry in this column, whereas a line division work center would have a high percentage. Maintenance functions which use large amounts of indirect labor cannot be expected to have high percentage in this column.

When evaluating the DIRECT LABOR column, the working environment, personnel assigned, and other similar factors must be considered. The location of a work center may cause its personnel to spend and excessive amount of time traveling to and from jobs. Naturally, this would reduce the manhours available for direct labor. Also, a work center with the majority of assigned personnel in the upper pay grades will ordinarily lose less direct labor manhours to absence categories than one with the majority of personnel in the lower pay grades.

Excluding staff type functions, indirect manhour expenditures usually decrease as the direct manhours increase. The reverse tends to be true when a light workload exists. Other factors which may lead to an increase in indirect labor expenditures are the performance of plant maintenance, the accomplishment of additional technical training within a work center, and the assumption of increased administrative duties.

Nonproductive manhours must be closely monitored, as these contribute little or nothing to the maintenance effort. The manhours listed in the two ABSENCE columns represent those not available to maintenance as a result of watches, inspections, nonmaintenance training, special liberty, leave, etc. Manhours of this type are a direct drain on the manpower resources of a work center and, therefore, must be closely watched to prevent them from becoming excessive and seriously impairing the productivity of the work center.

If the work center is adequately staffed, the workload properly scheduled, and the amount of absence manhours is reasonable, the expenditures shown in the OVERTIME column will be small. An abnormally high utilization of overtime, unless caused by an unpredicted workload, is usually a signal of an unbalanced condition within the work center.

As previously stated, the manhours entered in the MDR column represent those manhours documented by the work center on MDR forms. Ideally, total production manhours should equal the number of hours of available direct labor shown in the DIRECT column. A significant variance between the MDR and DIRECT columns indicates failure of the work center to correctly submit manhour accounting cards for exceptions from assigned direct labor or failure to correctly document production manhours on MDR forms. Therefore, complete and accurate MDR and MHA reporting is essential and must be stressed accordingly.

A management evaluation chart should be accompanied by a brief, written narration. The purpose of this narration is to point out areas of special interest, call attention to significant deviations from desired standards, and give credit for good performance when due.

A chart of this type may be used in either an Organizational or Intermediate level maintenance activity.

PERSONNEL UTILIZATION CHART

A personnel utilization chart is designed to show the utilization of the manhour assets within an activity in the terms of broad categories of labor. This type of chart could be used by both Organizational and Intermediate maintenance activities. The purpose of a chart of this type is to provide the commanding officer an overall picture of how his personnel are being employed and to allow comparisons of current utilization rates with predetermined goals. Figure 5-5 illustrates a personnel utilization chart for a squadron maintenance department. Discussion of the chart is contained in the following paragraphs.

The source of data for this type chart is MHA 4 and MDR 2. The direct labor (MDR) is the total number of manhours expended by all work centers that were documented on MDR source documents. These are listed in MDR 2. The indirect plus nonproductive labor is the sum of available productive indirect (600) and nonproductive (700) manhours. The absence manhours include the sum of duty absence (800) and nonduty absence (900) manhours less overtime manhours reported for these labor codes. Variance represents the difference between available direct labor manhours and MDR manhours. It is obtained by subracting the total MDR manhours from the available direct manhours. The total assets include the sum of net assigned and overtime manhours less overtime reported in absence labor codes.

14304

PERSONNEL UTILIZATION CHART ACTIVITY: VA-196 PERIOD: 1 through 30 May 1968

LABOR CATEGORY	MANHOURS
DIRECT LABOR (MDR)	15,910
INDIRECT PLUS NON-PRODUCTIVE (LC 600-700)	7,679
ABSENCE (LC 800-900)	4,569
VARIANCE (LC 500 LESS MDR)	360
TOTAL ASSETS:	28,518

COMMENTS: DIRECT LABOR PERCENTAGE SHOWS IMPROVEMENT OVER PREVIOUS MONTHS; HOWEVER, THE 1.3% VARIANCE INDICATES THE POOREST DOCUMENTATION SINCE IMPLEMENTATION OF THE 3-M SYSTEM.

SOURCE: MHA 4
MDR 2

AZ.17

Figure 5-5.—Personnel utilization chart.

The utilization percentages shown in the actual chart in figure 5-5 are obtained by dividing the manhours employed in each labor category by the total assets. In most cases, MDR manhours are less than available direct (500) labor. Therefore, a variance exists. The variance percentage is obtained by dividing the variance manhours by the total assets and the segment is plotted to the left of the chart centerline.

NOTE: In the event the MDR manhours exceed the direct labor manhours, the sum of direct, indirect, and absence manhours will exceed total assets (100 percent utilization). This variance is indicated as a broken line to the right of the chart centerline.

The personnel utilization goal (fig. 5-5) is used for training purposes only. The standards, or goal, applicable to a given activity are established by appropriate authority. In determining these standards, the following factors must be considered:

1. The primary objective of a maintenance activity is the upkeep and repair of aircraft and related equipment; therefore, the direct labor output of an activity (production manhours documented on MDR forms) must be in alignment with the anticipated workload.

2. Indirect labor expenditures are recognized as essential, but should be held to a minimum. Excessive housekeeping costs have an adverse effect on the direct labor output and can lead to unwarranted overtime.

3. A just portion of the manhour assets should be allocated to absence categories in order to provide for military duty, leave, etc. However, losses to absence should not be allowed to reach unreasonable proportions.

14305

Comparison of the actual distribution of utilized manhours to the established goal will reveal any differences as far as broad divisions of labor are concerned. Such differences may require further study and research to find the cause.

Although not designed to deal with other than general categories of labor, a chart of this type may be expanded to a limited extent. For example, the indirect plus nonproductive segment may be separated into indirect and nonproductive. Likewise, the absence segment may be further divided as duty and nonduty.

UTILIZATION OF OVERTIME MANHOURS

In order to provide Organizational and Intermediate maintenance managers with information concerning the utilization of overtime manhours, a chart similar to that illustrated in figure 5-6 may be used. This chart is designed to show not only the overtime spent by the maintenance department, but also overtime expended in absence status such as watches, inspections, etc. Figure 5-6 represents a squadron maintenance department application.

The source of data for this type chart is MHA 4. The total bar includes total overtime spent in all labor codes. The direct bar consists of overtime spent in direct (500) labor code. The indirect bar consists of the overtime spent in production indirect (600) labor codes. The nonproductive bar represents the overtime spent in nonproductive (700) labor codes. The absence bar consists of overtime spent in duty absence (800) labor codes.

The various percentages are obtained by dividing the total overtime and the overtime reported for each labor category by the total assigned manhours.

Overtime percentage considered acceptable for a given activity must be determined by the commanding officer. Percentage actually utilized compared to a standard will determine if expenditures are within a desired limit. If overtime is excessive, a detailed breakout, by

COMMENTS: OVERTIME MANHOURS EXPENDED ARE HIGH DUE TO THE REQUIREMENT FOR ADDITIONAL SECURITY WATCHES ON SQUADRON GEAR PACKED FOR DEPLOYMENT.

SOURCE: MHA 4

AZ. 18

Figure 5-6.—Utilization of overtime manhours chart.

14306 14305

labor code, may be required to isolate the labor code causing the condition. The absence overtime indicates those manhours spent after normal working hours, or on nonworking days, in the performance of nonmaintenance functions such as watches and inspections. Above normal expenditure of overtime in this labor category is of concern to management, from both the standpoint of morale and the loss of potential maintenance manhours.

COMPUTATION OF JOB AVERAGES

The average number of manhours required to accomplish a specific job is often used in conjunction with manning studies, workload scheduling, and similar managerial applications. Job averages may pertain to a simple remove and replace action or encompass the entire look phase of a calendar inspection. Job averages may be limited to the manhours contributed by a single work center or include the manhours documented by all work centers. Local needs dictate the actual extent of a particular job. The source of data for this type of computation is MDR 5. A typical method of computing a job average when only one work center and one maintenance action are involved is discussed in the following paragraph.

First, the applicable work unit code, action taken code, and malfunction description code defining the job must be determined locally. The items processed and the manhours shown on all lines listed for the specific job as defined above are then extracted from MDR 5. The job averages are obtained by dividing the total manhours by the total items processed. The reliability of the computed average is influenced by the amount of data used in the computation. To insure best results, statistics for an extended period of time should be used.

SHOP REPAIR DATA TABLE

The ability of an IMA to repair aircraft components efficiently and return them to RFI status for subsequent issue has a direct bearing on the aircraft operational readiness of supported activities. The IMA maintenance officer is constantly aware of production effort and initiates timely action to insure that an acceptable level of production is maintained. A presentation, similar to the shop repair data table shown in figure 5-7, provides the IMA maintenance officer with information to monitor the repair program and shows where he might increase maintenance repair capabilities.

NOTE: The line numbers, to the left of the action taken code column in figure 5-7, are used only for training purposes and to simplify the following discussion. The lines on an actual table of this type would not be numbered.

All data elements required to construct a table of this nature can be extracted from MDR 8-3. Lines 1 through 14 contain the double asterisk total for each action taken code for each work center. To obtain the total items processed by each work center, the entries in lines 1 through 14 are added and the sum entered in line 15. Line 16 contains the total number of items returned to service by each work center. This is the sum of action taken codes A, B, C, and Z. Line 17 contains the percentage of items processed within each work center that were returned to service. This is obtained by dividing the entry in line 16 by the total items in line 15 and multiplying the quotient by 100.

The total column contains the total items recorded by all work centers for each action taken code. The percent of total column contains the percent of total for each action taken code. This percent is obtained by multiplying the total column, for each action taken code, by 100 and dividing this product by the total of all items processed (line 15, total column).

A trend chart similar to the one illustrated in figure 5-8 may be constructed in conjunction with a shop repair data table. A chart of this type provides management with information on the total items processed and the number and percent of items returned to RFI conditions.

The source of data for this type trend chart is MDR 8-3. The number of months portrayed is normally determined locally; however, sufficient time should be shown to establish a definite trend. The figures used for the month of May in figure 5-8 are the same as those in the total column, lines 15, 16, and 17 of figure 5-7. Although some identical data may be contained in a shop repair data table and a components returned to RFI status trend chart, a table only provides information concerning one month, whereas a trend chart can provide data for several months.

These two analysis products are only a few of the many that can be obtained from the data contained in MDR 8-1 through 8-4. The number and type of components received for which no repair is authorized and the number

14307

TOPIC 2: CONSTRUCTION TECHNIQUES

Competencies

- Lay pattern on fabric and cut out pieces.
- Use staystitching.
- Make fullness in garment.
- Use proper seam construction.
- Pin-fit garments.
- Use hand and machine techniques for basting and removing stitches.
- Join garment parts.
- Apply a variety of interfacings.
- Apply a variety of facings.
- Understitch edges.
- Bind and pipe garments.
- Make different kinds of buttonholes by hand and machine.
- Measure, mark, and sew all types of hems.
- Cuff trousers.
- Line a variety of garments.
- Attach findings.
- Make various kinds of belts.
- Make fasteners.
- Apply commercial trimmings.

Motivating Procedure

Display mockups of various types of construction techniques. Have trainees turn in a list of techniques for which they will need instruction.

Learning Experiences

- Demonstrate and/or use filmstrips to show selected construction techniques.
- Have trainees develop new or improve their sewing skills by constructing a garment for own use, constructing garments for class use, or

of components processed that require no repair are other areas which may be analyzed by IMA analysts.

AIRCRAFT READINESS CHART

There are several methods of presenting the results of analysis in the area of aircraft readiness. These presentations provide management with a picture of operationally ready hours and percentage as well as hours and percentages not operationally ready maintenance (NORM) and not operationally ready supply (NORS). Figure 5-9 illustrates an aircraft readiness chart in the form of a pie chart.

The source of data for this type chart is ASD 3. The percent operationally ready is obtained by dividing the number of ready hours by hours IN NOR reporting status. The percent not operationally ready supply is obtained in a similar manner. The NORS hours are divided by the hours IN NOR reporting status. Likewise, the percent not operationally ready maintenance is obtained by dividing the NORM hours by the hours IN NOR reporting status.

An aircraft readiness chart provides management valuable information. If the percent of readiness is not considered acceptable, further analysis may be required to determine what factors have created this situation.

The fact that all aircraft must be periodically grounded for calendar inspections must be considered when performing analysis on NORM hours. However, if an unusual percentage is noted for this category, improper scheduling of inspections or other faulty practices may prevail.

COMMENTS: THE TREND OF COMPONENTS RETURNED TO AN RFI STATUS HAS REMAINED AT ABOUT 65% SINCE APRIL 1968.

SOURCE: MDR 8 3

AZ.20

Figure 5-8.—Components returned to RFI status trend chart.

Also, unscheduled maintenance should be analyzed on the basis of individual aircraft to determine if excessive unscheduled maintenance is predominant in all aircraft, or is restricted to selected aircraft. This may be accomplished by the construction of a table in which each bureau number is listed and the percent NORS, percent NORM, and percent operationally ready is computed and listed for each aircraft. Excessive unscheduled maintenance for all, or a majority of assigned aircraft, may indicate improper maintenance practices, improper workload scheduling, or improper quality assurance.

In order to monitor aircraft readiness on a daily basis, trend charts reflecting daily aircraft operationally ready and not ready time may be constructed by the analysis division and integrated into local management programs. The concept behind the design of a chart of this type is to provide interested personnel a ready means of reviewing the daily and cumulative operationally readiness trend.

Should this trend fall below established standards for the aircraft model maintained, additional analysis may be required and charts constructed to provide visual evidence of the factors causing the decreased readiness. Not operationally ready supply and not operationally ready maintenance are two areas which could be selected and displayed as possible problem areas. The required data elements for preparation of charts of this nature are found in ASD 2 and local records.

Although charts such as those mentioned above do not solve past problems, they can help forecast possible future problems. When the midpoint of the month has passed, a cumulative percentage below the standard is difficult to bring back up. By using these analysis products, management is kept current on operationally readiness percentage and can take appropriate action to correct problems when they first appear, rather than waiting until the percentage slips below established standards.

1430

AIRCRAFT READINESS CHART ACTIVITY: VP-9 PERIOD: 1 through 30 May 1968

TYPE EQUIPMENT: P-3A TOTAL HOURS POSSESSED: 8640

COMMENTS: OPERATIONAL READINESS IS STILL LESS THAN THE MINIMUM DESIRED; HOWEVER, IT IS AN IMPROVEMENT OVER PREVIOUS MONTHS. THE PERCENT NORS IS HIGHER THAN DESIRED. WITH IMPROVED LOGISTICS SUPPORT, THE ENTIRE PICTURE WOULD BE IMPROVED.

SOURCE: ASD 3

ABORT MALFUNCTIONS CHART

The failure of assigned aircraft to fulfil their scheduled mission (abort) because of malfunctioning equipment is a matter of considerable concern to management. Through the use of data contained in the MDR system, management can be informed of the aircraft systems or components causing these aborts, the number of items involved, when the abort malfunctions occurred, and similar information. The data may be employed to initiate investigation of circumstances leading to aborts. The abort malfunctions chart illustrated in figure 5-10 represents a typical method of presenting this type of data for an Organizational maintenance activity which accomplishes no component repair.

The chart shown in figure 5-10 is divided into three sections, and each section provides different information on the total number of aborts. All the data elements required to construct a chart of this type can be extracted from MDR 6. Prior to any data extraction, MDR 6 must be purified by elimination of entries which do not apply. This is accomplished by lining out those entries listing action taken codes 1 through 9, J, K, L, M, N, Q, T, U, and Y when used with when discovered codes A and C.

Section I of the chart contains information on when the abort malfunctions occurred or were discovered. The total abort malfunctions include the sum of items processed with when discovered codes A and C. The before flight abort malfunctions are the sum of items processed with when discovered code A. The in-flight abort malfunctions are the sum of items processed with when dicovered code C.

Section II contains information on the number of abort malfunctions by system. The figures in this section are obtained by determining the number of items processed with when discovered codes A and C within each system. The various systems are identified by the first two positions of the work unit code.

14310

COMMENTS: MOST OF THE BEFORE FLIGHT ABORTS WERE CAUSED BY IMPROPER PREFLIGHT INSPECTIONS. AN EXTENSIVE PREFLIGHT INSPECTION TRAINING PROGRAM HAS BEEN RECENTLY IMPLEMENTED.

SOURCE: MDR 6

AZ.22

Figure 5-10.—Abort malfunctions chart.

Section III contains information on the number of abort malfunctions requiring maintenance actions. The number of abort malfunctions requiring maintenance is the sum of items processed with when dicovered codes A and C, except those listed in conjunction with action taken code A. The number of abort malfunctions requiring no maintenance is the sum of items processed with when discovered codes A and C listed in conjunction with action taken code A.

This particular chart does not identify the number of aircraft aborts occurring during the month. The figures represent only the reported number of items or malfunctions involved in aborts. In numerous cases more than one item or malfunction may be attributed to the same abort. Weather and other factors may also cause aborts.

Possible trouble areas may be revealed by study of the data. A high number of malfunctions being discovered before flight may indicate inadequately daily or preflight inspections. Numerous defects in a certain system may point out a need for engineering changes. A substantial number of reported malfunctions which require no maintenance may be an indication of poor troubleshooting techniques or improper equipment operation.

CANNIBALIZATION TREND CHART

Under ideal conditions, with a well-organized maintenance department and adequate supply resources, there would be little need for cannibalization. However, ideal conditions do not always exist, and it may be necessary to resort to cannibalization. The cannibalization trend chart illustrated in figure 5-11 is one method of informing the maintenance officer of the extent of cannibalization actions within an activity. Reduction or elimination of these actions is of prime concern to maintenance managers. Not only is a shortage of parts evidenced, but an added manhour expenditure is incurred in

1431

removing and replacing the cannibalized items.

The source of data for this type chart is MDR 5. The total items cannibalized are obtained by selection of the total items processed listed for action taken code T. The total number of manhours spent in cannibalization is obtained by selection of the total manhours listed for action taken codes T and U.

The total items cannibalized are plotted on the chart and also listed under the respective month. By connecting the plotted points with a line, an increase or decrease in the number of cannibalized items over a specified period of time is readily visible. The number of manhours spent in cannibalization is also entered to provide management with information on the actual number of manhours expended in cannibalization actions.

A chart of the high five cannibalization items may be constructed in conjunction with a cannibalization trend chart. The data for a chart of this nature can be extracted from MDR 5. The high five cannibalized items should be selected on the basis of the number of times a specific item was cannibalized during the reporting period. Selected items can be presented in tabular format with the work unit code, nomenclature, type equipment, manufacturer's code, part number, and numerical frequency (total number of times the particular item was cannibalized during the month) listed for each item.

The review of a cannibalization trend chart will reveal the overall status of cannibalization within an activity. An increase in the rate of cannibalization is of immediate concern to management. Those items which are frequently cannibalized may merit special investigation to determine the cause.

PROBLEM REFERRAL MEMORANDUM

While performing analyses or during the screening of reports, an analyst may discover

CANNIBALIZATION TREND CHART ACTIVITY: VF-11 PERIOD: JAN. through SEPT. 1968

MONTH	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC
(1) TOTAL ITEMS	23	20	18	18	17	15	8	6	6			
(2) TOTAL MANHOURS	88.0	78.5	62.0	82.0	57.0	63.5	32.0	30.5	22.5			

(1) TOTAL ITEMS REMOVED FOR CANNIBALIZATION.
(2) TOTAL MANHOURS INCLUDE MANHOURS EXPENDED FOR REMOVAL AND REPLACEMENT AFTER CANNIBALIZATION.

COMMENTS: CANNIBALIZATION HAS BEEN ON A STEADY DECREASE SINCE JAN. AND STABLE FOR THE LAST THREE MONTHS.

14312

problems that are not of general interest. These may not warrant management attention; however, they should be brought to the attention of appropriate personnel so corrective action can be taken. A problem referral memorandum similar to that illustrated in figure 5-12 may be used for this purpose.

16 June 1968

From: Analysis Division
To: Work Center 410 (Attn: Chief Smith)

Subj: Erroneous Recording of Type Maintenance

Background: Machine reports indicated erroneous entries in type maintenance column. Type maintenance B (unscheduled maintenance) was used for work performed during a calendar ODD inspection. The correct type maintenance code is P.

(1) Daily reports revealed this was documented against BUNO 148221 on the following Julian dates: 8157, 8158, and 8159.

Conclusion: Training is required in the use of type maintenance codes.

14313

MAINTENANCE SUMMARIES

The most widely accepted method of publishing results of maintenance data analysis is through the use of monthly maintenance summaries. A maintenance summary is a publication produced at the local level on a periodic basis and contains charts, graphs, tables, and narrative briefs portraying the maintenance effort since previous publication.

Summaries are often geared to what the analyst feels is required information; however, this is not the desired standard. Instead, summary contents should be based on the concept of what management wants to know. The maintenance officer describes the scope of information required, and the summaries should be geared to these requirements. These requirements include, but are not limited to, analysis of the following subject areas:

1. Utilization and productivity of the labor force.
2. Efficiency of the entire maintenance operation.
3. Direct support cost per flying hour, sortie, or departure.
4. High manhour consumers.
5. High failure rate components.

Many additional subject areas which may, at the option of the preparing activity, be included in the summary as follows:

1. Cannibalization.
2. Malfunctions causing aborts.
3. Shop repair capability.
4. Manhour distribution.
5. Technical directive compliance program.
6. Distribution of possessed aircraft hours.
7. Manhours lost to nonmaintenance functions.
8. Overtime expenditures.

Figures which simply repeat machine reports should not be included unless there is a significant reason for doing so. The use of complicated charts, graphs, and tables should be avoided. Extensive use should be made of narrative briefs. These briefs should be arranged in such a manner that both the display and the brief are visible to the reader at the same time. The format selected for maintenance summaries should be tailored to the needs of the activity concerned. Maintenance summaries should be distributed to all work centers in the preparing activity and to all other interested parties as desired. The contents of maintenance summaries should be evaluated frequently—at least every 6 months.

Maintenance summaries are forwarded to the appropriate air type commander as well as other activities in the chain of command. These commanders have promulgated instructions which prescribe the reporting format and submission requirements of maintenance summaries for activities in their areas of control. These summaries are designed to present summarization of key data to facilitate management appraisal by local or higher levels of command. Some of the analysis products discussed earlier in this chapter are included in these maintenance summaries. Local maintenance managers may require summaries to include additional information from those prepared for higher level command distribution.

14314

Chapter 6

QUALITY ASSURANCE

As AZ's progress up the ladder of advancement, they will become more and more involved in the field of quality assurance. This does not necessarily mean that they will be quality assurance representatives or collateral duty inspectors, but it does mean that they should be quality conscious, as this is a requirement of everyone in an aircraft maintenance activity; especially those in supervisory capacities.

Properly functioning quality assurance divisions make it possible to determine deficiencies, analyze discrepancy trends, prescribe inspection procedures, determine quality of maintenance accomplished, and provide followup action and functional guidance to stimulate quality assurance on a departmental basis.

The quality assurance division is usually manned by permanently assigned, highly trained, technically competent personnel. The senior AZ may be assigned to a quality assurance division and, although not directly involved in actual maintenance or maintenance inspections, will play an important part in the maintenance organization. First Class and Chief AZ's supervise the operation of technical libraries and assist in other clerical functions of the quality assurance division. The senior AZ should have an understanding of the importance of quality assurance as it applies to aircraft and related equipment maintenance and be familiar with some of the functions of the quality assurance division.

CONCEPT OF QUALITY ASSURANCE

Fundamentally, the quality assurance concept is preventing the occurrence or recurrence of defects. This includes all events from the start of maintenance operations until their completion. Achievement of quality assurance depends on prevention, knowledge, and special skills.

Prevention relies on the principle that it is necessary to preclude maintenance failures. This principle extends to safety of personnel, maintenance of equipment, and virtually every aspect of the total maintenance effort. Prevention is concerned with regulating events, rather than being regulated by them.

Knowledge is derived from factual information. This knowledge is acquired through the proper use of data collection and analysis programs. The Maintenance Data Collection System provides maintenance managers unlimited quantities of factual information. Correct utilization of this information provides management with the necessary knowledge required to achieve maximum readiness of aircraft and weapon systems.

Special skills, not normally possessed by production personnel, are required of a staff of trained personnel for analysis of data and supervision of quality assurance programs.

The quality assurance program provides an efficient method for gathering and maintaining information on the quality characteristics of products and on the source and nature of defects and their impact on the current operation. It permits decisions to be based on facts rather than intuition or memory. It provides comparative data which will be useful long after the details of the particular times or events have been forgotten. Quality assurance requires both authority and assumption of responsibility for action.

A properly functioning quality assurance program will point out problem areas to maintenance managers so they can take appropriate action to accomplish the following:

1. Improve the quality, uniformity, and reliability of the total maintenance effort.
2. Improve the work environment, tools, and equipment used in the performance of maintenance.

14315

3. Eliminate unnecessary manhour and dollar expenditures.

4. Improve the training, work habits, and procedures of maintenance personnel.

5. Increase the excellence and value of reports and correspondence originated by the maintneance activity.

6. More effectively disseminate pertinent technical information.

7. Establish realistic material and equipment requirements in support of the maintenance effort.

In order to obtain full benefits from a quality assurance program, teamwork must first be achieved. Blending quality assurance functions in with the interest of the total organization produces a more effective program. Each worker and supervisor should be permitted to use an optimum degree of judgment in the course of their daily work, since an individual's judgment plays an important part in the quality of his work. Quality assurance techniques supply each person with information on actual quality. This information provides a challenge to the individual to improve the quality of his work. The resulting knowledge encourages the best efforts of all maintenance personnel.

Quality assurance is designed to serve both management and production equally. Management is served by quality assurance monitoring the complete maintenance effort of the department and furnishing the factual feedback of discrepancies and deficiencies. In addition, the action necessary to improve the quality, reliability, and safety of maintenance is provided. Production is served by having benefit of collateral duty inspectors formally trained in inspection procedures and in receiving technical assistance in resolving production problems. The introduction of quality assurance to the maintenance function does not relieve production of the basic responsibility for quality work; instead, that responsibility is increased by adding accountability. This accountability is the essence of quality assurance. It has long been recognized that quality and safety cannot be inspected into a job—that the worker completing the job assures quality—and that inspection confirms the presence or lack of quality to prevent deficient workmanship. In this regard, the inspection services provided by the collateral duty inspectors are an integral part of the production process. Under the proper concept of quality assurance, the quality of work is assured, not c[illegible]

MAINTENANCE QUALITY RESPONSIBILITY

Although the commanding officer is responsible for the inspection and quality of material under his cognizance, he must have the full cooperation of all hands to meet this responsibility. The responsibility for establishing a successful program to attain high standards of quality workmanship cannot be discharged by merely creating a quality assurance division within a maintenance organization. To operate effectively, this division requires the full support of everyone in the organization. It is the frame of mind of all personnel and not the instruments, instructions, and other facilities for inspection that determines the success or failure in achieving high standards of quality.

One of the major requirements for quality in maintenance is that the supervisors definitely understand that high quality work is a vital contribution to effective operation of any maintenance organization. To have high quality maintenance also requires that each worker understands not merely a set of specification limits, but also the need and intent for these limits.

The person with the most direct concern for quality workmanship is the production supervisor. This factor stems from his responsibility for the proper professional performance of assigned personnel. It is the direct responsibility of production supervisors to assign a collateral duty inspector at the time work is assigned. This procedure allows inspectors to make the progressive inspection required, instead of being confronted with a job already completed, functionally tested, and buttoned up. The completion of production work is not a function of the quality assurance division, and production personnel in the dual role of inspector cannot certify inspection of their own work.

The degree of quality attained in the aircraft maintenance department depends mainly on the training, supervision, and quality attitude of production personnel, and the proper use of current publications, backed by an effective inspection system. The mission of quality assurance can be realized only when it is continually and progressively exercised in all areas, and directed toward improvement of the NAMP.

FUNCTIONS

Due to variations in the mission of activities, and qualifications and numbers of assigned

14316

personnel, the quality assurance functions may be accomplished differently in each activity. In each case, however, the primary objective is the same—the prevention of the occurrence or recurrence of defects—and should be worked out within the guidelines, policies, and procedures provided in instructions such as NavAir Instruction 4700.2 (Series) and similar directives issued by type commanders.

The functions performed by a quality assurance division are varying and cover a wide area. It is not appropriate that all of them be discussed here. The following sections cover some quality assurance functions of concern to AZ's. It should be kept in mind that senior AZ's may be assigned to the quality assurance division of a maintenance department and perform/assist in the performance of some of these functions.

DATA COLLECTION AND TREND ANALYSIS

Trend analysis is one tool that may be used by the quality assurance division. Properly used, it furnishes maintenance managers factual information in order to get to the root of a particular problem. This problem may be the abnormal use of a particular part or component, the excessive utilization of manhours in the completion of a maintenance task, etc. The information furnished permits maintenance managers to make decisions and take appropriate action based on facts rather than thoughts or intuition. Maintenance managers may request trends in a particular problem area on a one-time or continuing basis.

By careful and continuous reference to completed MAF's, registers, yellow sheets, etc., many times a definite trend in discrepancies can be detected. Detection in itself is not difficult. The big problem is reducing these indications to basic causes or reasons for such trends. Sometimes they can be traced to improper maintenance procedures such as a misalignment caused by maintneance personnel not adhering to specifically outlined procedures. Perhaps the problem will be revealed by an investigation of test equipment being used. Such an investigation might disclose improper operation of test equipment. It may be found that error tolerances have been exceeded. Other times an equipment deficiency, especially in newer type equipments, can be "pinned down" as the reason. No matter what the cause, an analysis of the problem is required when a trend in discrepancies is noted.

The first step in trend analysis is the collection of factual data. This data is of little value unless it is accurately collected and used properly. The following are a few of many sources of data that may aid in the analysis of maintenance difficulties:

1. Completed flight schedules.
2. Recurring discrepancies file.
3. Test flight checksheets.
4. Various MDCS reports.
5. Completed registers.
6. Processed MDR forms.
7. Yellow sheets.

Individually, these sources mean little, but collectively they can indicate and reflect the pulse of the maintenance process.

After the data has been collected, it must be arranged in some fashion before the analysis can start. This arrangement may take many forms, dependent upon the type of data, complexity, amount, and the use to which the data is to be put. There is no standard format for the presentation of collected data; however, the one used should be easily understood and clearly point out the minor as well as the major problems. Various charts and graphs are widely used to portray this data.

The underlying causes of faulty workmanship and material failure can be classified into either of two categories: chance variations or assignable variations. Chance variations occur in a random manner and cannot generally be associated with any continuing causes; for example, compressor being hit by foreign object. Assignable variations occur in a definite pattern, and the source of these variations can usually be found and corrected; for example, faulty overhaul or manufacture of a series of parts. It is desirable to control both of these factors, but because of the nature of chance variations, control is essentially impossible; however, they can be detected and an estimate made of their future occurrence. The problem therefore resolves itself into one of determining the assignable variations.

The evaluation and analysis function of quality assurance involves reviewing the various charts and graphs, noting the values that are excessive, and searching for causes of these variations. The search involves a detailed review of the collected data until a logical reanswer can be found.

This review may bring to light such things as operable aircraft being erroneously grounded

14317

making parts of a garment such as setting in a sleeve, cuffing trousers, and applying a zipper. Have trainees use score cards to evaluate their sewing techniques. See Appendix G.

- Plan a field trip to several stores to compare the construction techniques used on clothing of different quality. Discuss the factors that determine the techniques used for garment construction.

Instructional Materials

- Mockups and examples of standard construction techniques
- Wall charts and filmstrips showing specific construction techniques
- Fabric for practice experiences
- Score cards for evaluating sewing techniques

1429

due to the lack of knowledge about a particular item by the operator. One solution to this problem is the pilot's discrepancy report, which is prepared and sent to a pilot when it is noted by his discrepancy that he lacks a complete knowledge of the aircraft component in question.

Trend analysis can be completed in many areas of aircraft maintenance departments. Close surveillance of the manhours expended in performing calendar periodic inspections can be maintained by use of a chart or graph. By monitoring the chart/graph, any trend can be noted and appropriate action taken.

Trend analysis may be completed to find out why improvement was noted in a particular area as well as why some particular item fell short of its expected goal. In all cases, the important thing is that the information gained be passed on to others.

MAINTENANCE DIRECTIVE REVIEW

The quality assurance division has the responsibility for reviewing all incoming technical publications and directives affecting the department and determining their application to quality assurance as well as their applicability to the particular organization.

Numerous maintenance directives are received by the quality assurance division. Most of these directives come from the NavAirSysCom, although some, concerning specific applications, are received from the type commander or other authority. In any case, all maintenance directives received should be promptly reviewed by appropriate quality assurance personnel so that they are cognizant of the action required in the event that production division personnel encounter difficulty in interpreting the information or require technical assistance.

Letter type technical directives such as airframe changes, airframe bulletins, accessory bulletins, etc., are published in a standard format. Still other maintenance directives are promulgated as instructions. Regardless of the type received, reviewing to determine applicability and the appropriate action to be taken is a relatively simple task.

Some of the directives received will apply to the type of aircraft and equipment being maintained; others will not. One of the first steps in maintenance directive review is finding out the applicability of the directive. For letter type directives the "application" paragraph states to what aircraft/equipment the directive applies. If only certain bureau numbers or serial numbers are affected, they will be listed in this paragraph. Directives of this type normally furnish some background information or give a reason for the directive. The "compliance" paragraph states the level of maintenance to which the directive applies and also the time limit for compliance. The necessary kits, parts, and materials required for compliance are listed under the "supply data" paragraph as well as their source. The step-by-step procedures to be followed in accomplishment of the directive are stated in the "detailed instructions" paragraph.

Although the quality assurance division performs review actions on maintenance directives to determine applicability and required action, the maintenance control work center is responsible for initiating action for compliance with maintenance directives. This includes planning, scheduling, and actual assignment for completion. The Technical Directive Compliance Form is used to initiate action and document all technical directive maintenance actions.

Some maintenance directives received need further interpretation and amplification before compliance. This is accomplished by the preparation of a Maintenance Instruction.

MAINTENANCE INSTRUCTION PREPARATION

Maintenance Instructions are locally prepared directives used to amplify or interpret directives received from higher authority or implement local instructions. They are issued on NavAir Form 4710/7 in the form of a SAMI, CAMI, or TIMI. The requirement for any Maintenance Instruction will normally be determined by local policy.

Maintenance Instructions are usually prepared by the division/branch concerned, which in some cases may be quality assurance. All Maintenance Instructions should be reviewed by the quality assurance and the maintenance/material control officer prior to their approval by the maintenance officer.

Care must be exercised in the preparation of a Maintenance Instruction as it is a tool by which the division officer directs his personnel. Preparation consists of more than just copying the maintenance directive. Quite often lengthy directives are received in which only certain parts have local application. In these cases the applicable portions should be selected,

14318

elaborated on or condensed as appropriate, and then written in a form that will meet the needs of the local activity. On the other hand, brief directives may be received which require considerable research work and amplification before they are understandable by production personnel.

Maintenance Instructions requiring the accomplishment of a particular task may be amplified by the use of an illustration. This is done by reproducing an appropriate illustration from the applicable technical manual showing the exact work area. The illustration is attached to and becomes a part of the Maintenance Instruction. Considerable research time may be saved for the production personnel if this method is used.

At times it may be appropriate to attach an extra or reproduced copy of the directive, on which the instruction is based, to the Maintenance Instruction. This provides those concerned with background information that might not be included in the Maintenance Instruction.

INSPECTION TECHNIQUES

The term inspection in the operating forces is related to procedures governing the determination of maintenance work to be performed on aircraft, engines, and related components. Inspection in this sense refers essentially to technical requirements or specifications and answers the question: What must be done to maintain aircraft material readiness? The term inspection with respect to quality assurance is a different term. Essentially, it refers to the completeness of work and answers the following questions:

1. Are responsible personnel performing quality workmanship on the items maintained?
2. Are applicable technical specifications being carried out?
3. Are there discrepancies which have not been covered by applicable specifications and which require immediate attention for safety of flight?

Another traditional usage of the term inspection denotes the acceptance portion of the quality assurance function and, based on a set standard, approves or rejects equipment for operational use. Collateral duty inspectors usually perform this inspection. It should be accomplished during and after the completion of a maintenance task. Inspections in this sense refer to the completeness of work.

Another type of inspection, known as a maintenance evaluation, is performed when analysis of collected data indicates that such action is appropriate. Statistical quality assurance encompasses the prevention portion of quality assurance, using the data generated by inspection to indicate areas requiring action to prevent quality falling below established standards. It also provides a confidence factor in that discrepancy data is used to determine that the quality of conformance is satisfactory. This inspection is conducted by the quality assurance representatives, and it is actually a comprehensive evaluation of the elements comprising the complete maintenance task under consideration. The objective of maintenance evaluations are to determine: (1) if the systems, procedures, and equipment used in the productive effort are such that quality workmanship will be accomplished, and (2) areas where changes can be recommended to improve the quality of the products of the activity.

The organization of the quality assurance function is made up of three main components—acceptance, prevention, and confidence. The ideal arrangement would be to have quality assurance wholly within the quality assurance division. However, in maintenance departments it is usually necessary to accomplish the acceptance portion of quality assurance through inspections by inspectors from the production divisions. The quality assurance divison need not function as an inspection service division for the department; but must, however, concern itself with the prevention and confidence portions of quality assurance.

Accomplishing tasks through inspection of the department output is within the concept or scope of the quality assurance mission. Assuring the quality of work accomplished by the department requires a considerable number of personnel and will, in effect, duplicate the normal inspection conducted by the inspectors within the production divisions. Both routine inspections by production inspectors and quality assurance representatives are aimed at insuring the quality of the production output. The objective of production is to determine if a particular product or job meets a specified quality standard. The objective of the quality assurance inspection is to determine whether or not the systems, procedures, and equipment used in the production effort are such that quality workmanship will be accomplished.

OSCAL 14319

Quality Assurance Personnel

The nucleus of the quality assurance division is comprised of a group of quality assurance representatives. These permanently assigned representatives are, in most activities, supplemented by designated collateral duty inspectors. Collateral duty inspectors are those personnel permanently assigned to a production division who have a secondary or collateral duty assignment to inspect work accomplished within their assigned production division. The numerical balance between quality assurance representatives and collateral duty inspectors is at the discretion of the particular activity.

The need for quality assurance requires that only skilled mechanics and supervisors be designated as representatives/inspectors. Quality assurance representatives and collateral duty inspectors are highly qualified personnel with the ability to insure quality of maintenance within their technical areas. It must be recognized under this concept that the personnel in the production divisions are ultimately responsible for the quality of work performed in the department. Quality assurance representatives monitor production and insure that high quality workmanship is accomplished by maintenance personnel and that specifications and quality standards are met.

Quality assurance representatives are normally selected by the quality assurance division from all assigned maintenance personnel. Collateral duty inspectors are usually nominated by their respective division. These nominations are approved by the quality assurance division after determining that the nominee is fully qualified to inspect the work for which he is responsible. All personnel performing inspection functions are designated in writing by the commanding officer and their qualifications are reviewed periodically. One accepted method of determining an individual's qualifications is by locally prepared tests administered by the quality assurance division.

Personnel selected for representatives/inspectors should possess the following characteristics:

1. Skill, experience, and the ability to work with others.
2. The ability to read and interpret drawings, technical manuals, and directives.
3. Motivation and personal desire to develop greater knowledge of his technical speciality.
4. Stability and excellence in performance.
5. The ability to write with clarity and accuracy.
6. Observant, alert, and an inquiring nature.
7. A senior in grade and experience.

Even though quality assurance inspections conducted by designated quality assurance representatives are not accomplished on the total productive output of the department, an inspection, in most cases, is accomplished by an authorized collateral duty inspector on all completed work. Quality assurance is concerned with the completeness and adequacy of this inspection and emphasis is placed on the thoroughness of the inspections rather than the number of units inspected.

NOTE: Quality assurance representatives should inspect all maintenance tasks which, at their completion, require the aircraft to be flight tested.

TECHNICAL DATA

The NavAirSysCom furnishes aircraft maintenance activities with technical information and instructions necessary for the operation and maintenance of weapons systems and related equipment. Technical information and instructions are disseminated in the form of manuals and letter type material. To permit attainment of a satisfactory state of readiness, these publications are published and distributed in time to assure availability to users. By proper use of these publications, all aircraft and other aeronautic equipment can be operated and maintained efficiently and uniformly throughout the Navy.

When a new aircraft, weapons system, engine, accessory, or other item of equipment is accepted by the Navy, manuals necessary to insure its proper operation and upkeep are prepared and issued to all activities using and/or maintaining the equipment. Supplemental information and other directive type publications that must be issued from time to time are issued in the form of letter material. Both manual and letter publications may, on occasion, be properly referred to as directives. Broadly speaking, any communication which initiates or governs action, conduct, or procedure is a directive.

The primary purpose of technical publications is to aid maintenance personnel in accomplishing their work. They are written for and communicate information and direction to maintenance personnel in their own specific

14320

technical language. Technical publications are prepared by the prime airframe and powerplant manufacturers, by the manufacturers of specific equipments, and by the NavAirSysCom or its field activities, in accordance with specifications issued by the NavAirSysCom. They set forth current authoritative information concerned with material upkeep, check, test, repair, and operation in a manner to provide for optimum product performance. It is extremely important that all personnel responsible for the maintenance and operation of naval aircraft and associated equipment be thoroughly familiar with and use the publications provided in the daily execution of their maintenance tasks. The time has long since passed when maintenance personnel could properly perform their work without written technical aid or, at the most, after a thumbing through or a one-time reading of the related technical publication. Modern technology is a dynamic, constantly changing thing and requires continuous reference to and the use of the approved and provided ways and means of keeping technically current.

From the foregoing it can be readily seen that maintenance activities require large quantities of technical data for the proper operation and maintenance of aeronautic equipment. The technical library provides maintenance activities with a central point for the procurement and proper dissemination of this technical data. Since technical information is of prime importance in assuring the quality of work produced, the quality assurance division is responsible for operating the technical library. Another important task of senior AZ's is the supervision of the operation of technical libraries.

NAVAL AERONAUTIC PUBLICATIONS INDEX

All aeronautic publications are assigned a title and code number. When they are available for issue, all publications, except Instructions and Notices, are listed in the Naval Aeronautic Publications Index.

A complete Naval Aeronautic Publications Index consists of several individual publications, each of which serves a specific purpose. They are identified as follows:

Navy Stock List of Forms and Publications, NavSup Publication 2002, Section VIII, Parts C and D.

Equipment and Subject Applicability List, NavAir 00-500A.

Aircraft Application List, NavAir 00-500B.

Directives Application List by Aircraft Configuration, NavAir 00-500C.

A description of these lists and their uses is presented in the following paragraphs.

Navy Stock List of Forms and Publications

The Navy Stock List (NSL) of Forms and Publications (NavSup 2002) contains a listing of all forms and publications issued by the bureaus, systems commands, and offices of the Department of the Navy. NavSup Publication 2002 is a 13-section index; however, only two sections (II and VIII) are of primary concern to the AZ.

Section II lists all the forms used in the Navy. Section VIII of this stock list is the basic index of NavAirSysCom publications and contains a numerical listing of all available aeronautic publications by code number, title, security classification, and the date of latest issue. An additional column in Part C furnishes stock numbers for the different manual publications. An Air Force-Navy cross-reference index and a general alphabetical index are provided in the last sections of Part C.

The Numerical Index of Aeronautic Publications is made up of Parts C and D of Section VIII of NavSup Publication 2002. Part C contains a listing of manual type publications, and Part D contains a listing of letter type technical directives.

Part C is divided into subject matter groups, and all publications within a group are then listed in numerical order. For example, all manuals in the 00 series are listed first, then followed by the 01, 02, 03, etc., through the 51 series.

Part D is further divided into a number of subsections. Some of these include general, aircraft/airframe, accessories, powerplants, and support equipment. Listed in the general section are Aircrew System Bulletins and Changes, Aviation Clothing and Survival Equipment Bulletins and Changes, Technical Orders, and Technical Notes. All Aircraft/Airframe Changes and Bulletins are listed in the aircraft/airframe section. The accessories section contains a listing of all Accessory Changes and Bulletins. Engine Bulletins and Changes are listed in the powerplants section. The support

14321

equipment section contains a listing of all Support Equipment Changes and Bulletins.

The basic index (NavSup Publication 2002, Section VIII, Parts C and D) is revised and reissued annually. A separate supplement covering each Part is issued bimonthly between issues. The revision to the basic index, as well as each supplement, is cumulative from the prior revision.

Equipment and Subject Applicability List

The Equipment and Subject Applicability List (NavAir 00-500A) contains an alpha numeric listing of all aeronautic equipment by model, type, or part number and indicates all manuals by code number that are applicable to each item of equipment. In addition, another section of this list contains an alphanumeric listing by model, type, or part number of all aeronautic equipment by category (accessories, armament, clothing and survival equipment, etc.) and indicates by number all letter type technical directives applicable to each item of equipment.

Publication numbers appear more than once in this list inasmuch as complete equipment systems and their respective major components are listed separately.

This list should be used when attempting to determine what publications are available on a particular item of equipment, and the class of equipment, model, type, or part number are known.

This list is revised and reissued semiannually, in March and September. It is kept current by the issuance of bimonthly supplements between each basic issue.

Aircraft Application List

The Aircraft Application List (NavAir 00-500B) contains a listing of all manuals grouped according to their application to an aircraft. This part of the index does not contain listings of any letter type publications, and all manuals are listed by publication code number only.

A list of basic numbering categories is provided in the front of the book. This list may be used in determining the general type of equipment covered in a publication. It may also be used to determine what manuals are available for a particular model of aircraft.

This list is revised and reissued semiannually, in March and September and is not supplemented between reissues.

Directives Application List by Aircraft Configuration

The Directives Application List by Aircraft Configuration (NavAir 00-500C) contains a listing of the active NavAirSysCom letter type technical directives with respect to their applicability to aircraft. The lists in this volume are arranged first by aircraft series, second by aircraft configuration, and third by Airframe/Aircraft Bulletin and/or Change numbers. NOTE: Configuration refers to modifications made to a basic aircraft model. For instance, F-4A, F-4B, RF-4B, F-4G, etc., are all different configurations of the F-4 aircraft model.

This list is revised and reissued semiannually, in January and July and is not supplemented between reissues.

TECHNICAL MANUAL SYSTEM

Manuals are published in a number of different general subject categories. The AZ supervising the operation of a technical library should be familiar with all the various categories of manuals; however, this and the following sections are primarily concerned with the manuals most often used or required in aircraft maintenance activities.

Technical manuals for an aircraft model, its components, and support equipment normally consist of Periodic Maintenance Requirements Manuals, Maintenance Instructions Manuals, Structural Repair Manuals, Illustrated Parts Breakdown Manuals, Overhaul Instructions Manuals, Operating and Service Instruction Manuals for support equipment, a Maintenance Planning Manual, General Engineering Series Manuals, Training Manuals, and Special-Purpose Manuals.

General Manuals (00 Series)

As indicated by the title, this series of manuals includes information of interest to all naval aviation personnel. In the final analysis, some publications in this series may not be considered as actual technical manuals; however, they furnish aircraft maintenance activities with valuable required information. Included are three parts of the Naval Aeronautic Publications Index (00-500A, 00-500B, and 00-500C, already discussed), Outfitting Lists and Allowance Lists, and Aviation Training Literature.

ALLOWANCE LISTS AND OUTFITTING LISTS (00-35Q SERIES).—Allowance Lists and Outfitting Lists consist of listings of the material and equipment necessary to place and maintain various activities in a material readiness condition. These allowances are based on known or estimated requirements or on available usage data.

Allowance Lists are identified by SECTIONS. Certain sections such as A, H, and K are issued as individual publications. Others such as B, R, and T appear as a series of publications, each of which is applicable to a specific model of equipment, model of aircraft, or type of activity.

Allowance Lists are reissued periodically. When new issues or reissues are published, they are listed in the next issue of NavSup 2002, Section VIII, Part C. All lists not appearing in the current issue or latest supplement to NavSup 2002 have been canceled.

For the most part, Allowance List and Outfitting List code numbers are NA 00-35Q plus the section identification letter and a dash number to identify a particular section in the series. For example, a Section G Allowance List for the S-2D aircraft is NA 00-35QG-007. This publication lists all the accountable general support equipment necessary for the Organizational maintenance of the S-2D aircraft and some related aircraft models. The foregoing Allowance List is used in conjunction with NA 00-35 QG-016, which lists all consumable general support equipment for all classes, types, and models of aircraft.

Allowance Lists are discussed in detail in chapter 7 of this training course.

TRAINING LITERATURE (00-80 SERIES).—This series of publications is issued by authority of the Deputy Chief of Naval Operations (Air). Included are various Air Safety Pamphlets and General Aviation Training Publications. All such publications listed in the current issue of NavSup 2002, Section VIII, Part C, are available at the publications supply point. All requests for 50 or more copies of a publication must be submitted to the Chief of Naval Operations, Flight Training Branch, Washington, D.C. 20350, with a statement of justification.

Aircraft Manuals (01 Series)

The following types of manuals are prepared and issued for each model of aircraft used by the Navy:

NATOPS (Naval Air Training and Operating Procedures Standardization Program) Flight Manual, herein referred to as Flight Manual.

Maintenance Instructions Manual.

Structural Repair Manual.

Illustrated Parts Breakdown.

Periodic Maintenance Requirements Manual, including related Maintenance Requirements Cards and Sequence Control Charts.

The NavAirSysCom also provides a series of General Engineering Manuals, applicable to all aircraft models, and available to aircraft maintenance activities. These publications are concerned with such subjects as Corrosion Control, Aircraft Structural Repair, Aircraft Hardware, and Aircraft Cleaning. As previously stated, these publications are of a general nature and are used in conjunction with the specific aircraft model manuals.

A maintenance Planning Manual is issued (for newer models) to serve as the maintenance officer's source of information on maintenance management with respect to the particular weapons system. It contains information on what the total maintenance plan for the weapons system is, what facilities, equipment, material, space, and personnel will be needed, and what resources, including technical information, services, training, supply support, etc., are available and how to obtain them.

FLIGHT MANUAL.—The Flight Manual contains complete operating instructions for the aircraft and its operational equipment. Emergency operating instructions as well as normal operating instructions are provided. Although Flight Manuals are issued primarily for the use of pilots and aircrewmen, they provide valuable operational information to maintenance personnel as well.

Two methods of updating Flight Manuals are by regular change notices and by interim manual changes. Regular change notices are issued periodically and cover routine changes and instructions. Interim manual changes cover vital operating instructions and are issued when immediate action is necessary.

Flight Manuals for newer aircraft models are identified by -1 in Part III of the publication code. For example, NA 01-40AVC-1 identifies a Flight Manual for the A-4E.

MAINTENANCE INSTRUCTIONS MANUAL.—The Maintenance Instructions Manual (MIM) contains most of the essential information required by aircraft maintenance personnel for service and maintenance of the complete

14323

aircraft. It includes the data necessary for troubleshooting and maintaining the powerplant, accessories, and all systems and components of the aircraft.

Instructions in the Maintenance Instructions Manual include such typical service and maintenance operations as the following:

1. Routine servicing.
2. Lubrication requirements.
3. Cleaning.
4. Adjustments.
5. Minor repairs.
6. Removal and replacement of components.
7. Testing.

The Maintenance Instructions Manual for all current production aircraft is made up in volumes, each volume being individually bound and issued separately. This permits each work center in an activity to have its own applicable volume, or volumes, at hand for ready reference.

Classified maintenance information is not included in the regular volumes of the Maintenance Instructions Manual. Essential classified information is contained in separate volumes or supplements of the Maintenance Instructions Manual which are classified "confidential." These volumes are usually bound in red in order that they may be readily identified and should be handled in accordance with the Department of the Navy Security Manual for Classfied Information.

The various volumes of the Maintenance Instructions Manual cover such areas as the following:

General Information and Servicing.
Airframe Group.
Powerplant and Related Systems.
Armament and Photographic Systems.
Electrical Systems.
Communication and Radio Navigation Systems.

The first volume, usually titled General Information and Servicing, is designated primarily for the plane captain; however, this volume contains a great deal of information important to all maintenance personnel. It contains a general description of the aircraft, all information pertaining to servicing the aircraft, and necessary information which is not contained in other specialized volumes.

Each of the specialized system volumes (airframe, powerplants, electrical, etc.) of the Maintenance Instructions Manual is further divided into four sections, as described in the following paragraphs.

Section I is the same in all volumes of a particular aircraft Maintenance Instructions Manual. This section provides an introduction to the manual and usually supplies a list of the changes applicable to the particular volume concerned.

Section II describes the system and components as well as their operation.

Section III provides such maintenance coverage as removal and installation procedures and troubleshooting charts for the Organizational level of maintenance.

Section IV provides component repair procedures for the Intermediate level of maintenance.

The different aircraft manufacturers may group the material in the various volumes of the Maintenance Instructions Manual under different titles. For example, the Survival and Environmental Systems MIM for one model aircraft may be contained in one volume; whereas, another model aircraft may have two or more volumes to cover the same subjects.

As previously stated, the complete MIM for an aircraft consists of several separately bound volumes. Each volume is assigned an individual publication code number for identification purposes. The complete MIM is divided into groups of volumes (categories) containing related data or related systems.

Maintenance Instructions Manuals are identified by -2 in Part III of the publication code. Additional dash numbers are used to identify the different groups or categories. Point numbers are used to identify subsystems or related data to these groups or categories. For example, NA 01-75PAA-2-2.2 is the code number for the P-3A MIM for the Airframe Group, and NA 01-75PAA-2-2.2 signifies the MIM for the Landing Gear System for the P-3A.

STRUCTURAL REPAIR MANUAL.—This manual is prepared primarily for personnel of the AM rating and is used as a guide in making structural repairs to the airframe. It contains general information such as airframe sealing, control surface rebalancing, general shop practices, damage evaluation and support of structure, and a description of the structure through the medium of indexed illustrations and repair drawings.

The Structural Repair Manual for most new aircraft is published in two volumes. This is not due to its size but is to suit its usage by

14324

Powerplant Manuals (02 Series)

Powerplant Manuals, commonly called Engine Manuals, are designed primarily for the use of personnel in the AD rating; however, other maintenance personnel may require the use of these manuals from time to time. The 02 series manuals are broken down as follows:

02 applies to General Aircraft Engine Manuals.

02A applies to Reciprocating Engine Manuals.

02B applies to Jet Propulsion Engine Manuals.

02F applies to Rocket Type Jet Engines.

Generally, each engine model is covered by three types of manuals—Service Instructions Manual, Overhaul Instructions Manual, and an Illustrated Parts Breakdown.

Parts I and II of the publication code for these manuals are basically the same as the Aircraft Series (01). Part III of the publication code normally consists of a-2 for the Service Instructions, -3 for the Overhaul Instructions, and -4 for the Illustrated Parts Breakdown.

SERVICE INSTRUCTIONS MANUAL.—This manual contains information necessary for the routine servicing and maintenance of the engine model covered. Also included are instructions for troubleshooting, dismantling, reassembling, and testing the engine.

OVERHAUL INSTRUCTIONS MANUAL.—This manual contains instructions for complete overhaul of the engine as performed by Naval Air Rework Facilities. Although it is published primarily for overhaul activities, it is also used by Organizational and Intermediate maintenance activities.

ILLUSTRATED PARTS BREAKDOWN.—This is a parts catalog containing listings of all the parts of the complete aircraft engine. It is broken down into an Introduction, Group Assembly Parts List, and a Numerical Index. This manual illustrates, lists, and describes all parts and special support equipment necessary to maintain the particular engine model.

Aircraft Components and Related Equipment Manuals

These manuals are not limited to but include Accessories Manuals, Instrument Manuals, Armament Manuals, and Electronics Manuals. The 03 series manuals cover all types of accessories; Instrument Manuals are covered in the 05 series; the 11 series manuals are concerned with Armament and related equipment; and the 08 and 16 series pertain to Electronics Manuals.

The manufacturer of each item of equipment (carburetor, altimeter, bomb rack, radar set, etc.) is required to provide adequate instructions for operating the item and maintaining it throughout its service life. These manuals therefore contain descriptive data; detailed instructions for installation, operation, inspection, maintenance, and overhaul; and an illustrated parts list. All manuals pertaining to these different items of equipment available for issue are listed in numerical order (by publications number) in the applicable section of Part C, Section VIII of NavSup Publication 2002. They are also listed in 00-500A, but in alphanumeric order according to part number. In 00-500B, these manuals are listed under the aircraft in which the item is installed.

Aircraft components and related equipment manuals are used to supplement information found in the aircraft Maintenance Instructions Manual. For example, when the Maintenance Instructions Manual does not give instructions for repairing a particular item, reference should be made to the applicable item manuals.

If a component or piece of equipment is relatively simple, all the necessary instructions may be contained in a single manual. More complex items may require two or more manuals. For example, one manual may cover operation, service, and overhaul instructions, while the parts breakdown is contained in a separate manual.

Support Equipment Manuals (17 and 19 Series)

The 17 and 19 series of technical manuals cover most types of support equipment. The manufacturer of each item of support equipment is required to furnish adequate instructions for operating the equipment and maintaining it throughout its service life. Like aircraft Maintenance Instructions Manuals, these publications, prepared by the manufacturer, are issued under the authority of the NavAirSysCom and are then official Navy publications.

Support Equipment Manuals are stocked, cataloged listed, and located in the same manner as aircraft components and related equipment manuals.

14325
14326

Included in the 17 and 19 series of technical manuals are the Maintenance Requirements Cards for various ground support equipment.

Descriptive Data Sheets for
Aviation Support Equipment
(20 Series)

These sheets provide a consolidated source of descriptive information about individual items of aviation support equipment not available elsewhere.

The type of data furnished on these sheets includes the following:

Official nomenclature of the item.
Manufacturer and model/type number.
Functional classification.
Federal Stock Number.
A photograph or drawing of the item.
Functional description (purpose).
Reference data and literature available about the item.
Shipping data (size, weight, etc.).

LETTER TYPE TECHNICAL DIRECTIVES

BuWeps Instruction 5215.8 established a system to promote uniformity in technical directives. This system is limited to instructions of a technical nature which change or modify the affected aircraft or equipment. These instructions are disseminated in the form of Changes and Bulletins, or in special circumstances by Interim Changes or Interim Bulletins. NavSup Publication 2002, Section VIII, Part D, together with its latest cumulative supplement, provides a listing of all current letter type technical directives.

Changes and Bulletins are issued by technical personnel of the NavAirSysCom and are based on Contractor Service Bulletins, material defects submitted by field service activities, or other letters of recommendation of proposed modifications from field service activities.

Changes and Interim Changes are assigned numbers in a numerical sequence by the Technical Directives Control Center, located at the Naval Air Technical Services Facility (NATSF), Philadelphia, Pa. 19111. Bulletins and Interim Bulletins are numbered similarly in another number series. Since all Interim Changes are in one series and all Interim Bulletins in another, it is then possible to keep the same number for a formal Bulletin or Change when such is issued to supersede the interim directive.

Sometimes it is found that a Change or Bulletin is not the complete answer to a problem, and it is determined necessary to amend or revise an outstanding directive. An Amendment is used for minor changes in the original directive. A Revision is a completely new edition of an existing directive. Identification of revised or amended Changes and Bulletins is discussed in the following paragraphs.

The title of a Change or Bulletin for aircraft and powerplants is made up of four parts. Part one is the aircraft or powerplant model designation; part two, the appropriate title subject; and part three, the word "Change" or "Bulletin" and the sequential number. When applicable, the words "Rev. A," "Amendment 1," etc., follow the basic directive number.

The title of a change or Bulletin for equipment consists of only three parts—the title subject, the word "Change" or "Bulletin," and the sequential number.

Interim Changes and Bulletins are titled in the same manner as formal Changes and Bulletins with the exception that the word "Interim" is prefixed to the title. The title subject of a Change or Bulletin is one of the following, as appropriate:

Powerplant.
Propeller.
Airframe.
Avionics.
Accessory.
Aviation Armament.
Photographic.
Aircrew System.
Clothing and Survival Equipment.
Air Launched Missile.
Target Control System.

An Interim Change or Interim Bulletin is a directive issued to correct a safety or operational condition whenever it is considered too important to risk waiting for the issuance of the formal directive. Such directives are normally issued by message to insure speedy receipt by activities concerned. These directives may or may not contain the final solution to the condition being experienced.

Interim Changes and those Interim Bulletins which require continuing action are usually superseded by a formal Change or Bulletin with the same directive title and number within 90 days from the date of issue. Interim Bulletins

14327

TOPIC 3 - ALTERATION TECHNIQUES

Competencies

- Transfer markings of fitter for alteration.
- Pad out dressmaker's dummies to simulate figure problems.
- Adjust for fullness.
- Adjust neckline and facing to fit.
- Alter collars, neck, and neckfacings.
- Alter various kinds of sleeves.
- Alter shoulder line.
- Adjust fit of sleeve.
- Alter length of sleeve, jacket, coat, dress, skirt, and pants.
- Adjust back of garment.
- Alter lined garments.
- Correct waist line problems.
- Adjust waistband on skirts and pants.
- Alter hip line on skirt, dress, and pants.
- Fit and adjust crotch seam in pants.
- Alter cuffs.
- Make alterations on all types of fabric including suede, leather, fur, wool, vinyl, silk, and velvet.
- Establish good rapport with customer.

Motivating Procedure

Display on dressmaker's dummies a well fitting garment and a garment of the same style in need of alteration. Conduct a circular response on the desirability of correct fit and ways the poorly fitted garment may be altered.

Learning Experiences

- Demonstrate the principles of fitting with a garment on a dressmaker's dummy. Distribute Standards for Fitting Women's Clothes and have trainees evaluate the fit of garments worn by selected class members. See Appendix H.

of a single action nature are not superseded by a formal Bulletin.

Changes

A Change is a technical directive containing instructions and directions to accomplish a material change, modification, repositioning, or alteration in the physical appearance of an aircraft or equipment or the installation of different parts in subassemblies, assemblies, or components in aircraft or equipment. They may cover additions, omissions, or replacement of parts. They also cover any change in the material of which the parts are made. Airframe Changes are issued after delivery and acceptance of the aircraft by the Navy and are usually issued for the purpose of improving flight or safety conditions of the aircraft or equipment.

Changes are classified by various "action" categories. The assigned action category serves as a priority for compliance with the various directives.

The classification Immediate Action is assigned to directives which are issued to correct safety conditions, the uncorrected existence of which would probably result in fatal or serious injury to personnel, extensive damage, or destruction of property. These directives are identified by a border of red X's, broken at the top center of the page by the words IMMEDIATE ACTION.

The classification Urgent Action is assigned to directives which are used to correct safety conditions which, if uncorrected, could result in personnel injury or property damage. These directives are identified by the words URGENT ACTION at the top of the first page and a border of red diagonals around the cover page.

Routine Action directives are those concerned with equipment or procedural deficiencies of a material—mechanical, operational, or tactical in nature—the uncorrected existence of which could constitute a hazard. They are identified by the words ROUTINE ACTION printed at the top of the cover page.

Bulletins

A Bulletin is a technical directive containing instructions and directions to accomplish inspections, calibrations, tests, and adjustments, or additional instructions on standard rework, methods, limitations, and procedures which do not fall within the definition of a Change. A General Bulletin may be issued in instances in which the instructions and directions apply to a number of different powerplants, airframes, etc. Bulletins may be assigned an action classification like a Change, but this is not mandatory. A bulletin does not require the addition or deletion of parts. It may, however, require the replacement of the removed part with a new part of the same part number.

Instructions and Notices

Instructions and Notices are directives containing information and instructions concerning policy, administration, and air operations. As previously stated, Instructions and Notices are not listed in the Naval Aeronautic Publications Index. They are discussed further in chapter 3 of this training course.

MISCELLANEOUS AVIATION PUBLICATIONS

Several other publications of general interest to aviation personnel are available in most aircraft maintenance activities. A few of the most important are discussed in the following paragraphs.

Approach

Approach (NavAir 00-75-510), The Naval Aviation Safety Review, is published monthly by the Naval Safety Center and is distributed to all naval aeronautic organizations. It presents the most accurate information currently available on the subject of aviation accident prevention.

A large number of aviation maintenance accidents are maintenance induced; that is, they occur during preparation for, performance of, and securing from maintenance or as a result of sloppy or improper maintenance. For instance, a statistic reported in Approach revealed that in 9 accidents during a 15-month period, 9 aircraft were lost—9 million dollars lost due to the omission of 9 cents worth of cotter pins.

Digest of U.S. Naval Aviation Weapons Systems

The Naval Aviation Engineering Service Unit (NAESU), by direction of the Commander, Naval Air Systems Command, prepares and publishes

14328

a monthly magazine of interest and importance to aviation maintenance personnel. This magazine is published in two editions—Aeronautics (NavAir 08-1-504) and Avionics (NavAir 08-1-503).

The digest is sent to all naval aviation activities and other authorized agencies requiring information concerning current trends in naval aeronautical, electrical, and electronic equipments relative to operation, maintenance, installation, and supply. Both editions provide an excellent source of information dealing with new equipment and new ideas for older equipment. The articles in both editions are tailored to the needs of maintenance personnel.

The Aeronautics edition concentrates on subject matter that is maintenance oriented for aeronautical shops and work centers. Articles in this edition pertain to such subjects as powerplants, airframes, armament, and aviator survival equipment.

From the title, it is apparent that the Avionics edition is primarily devoted to the field of electronics. This edition gives the latest procedures for speeding the testing, calibration, and alignment of equipment, as well as new developments in avionics equipment and avionics maintenance problems.

Each activity should receive sufficient copies to provide at least one copy to each shop or maintenance work center. In addition, a file of back issues should be maintained in the technical library. Requests for additional copies, article reprints, and mailing list changes should be made directly to NAESU.

Naval Aviation News

The Naval Aviation News, NavAir 00-75-3, is published monthly by the Chief of Naval Operations and the Naval Air Systems Command. Its purpose is to disseminate data on aircraft training and operations, space technology, missile, rocket, and other aviation ordnance developments, aeronautical safety, aircraft design, powerplants, aircraft recognition, technical maintenance, and overhaul procedures.

As its name implies, this publication is essentially a news magazine. It enables readers to keep abreast of the latest unclassified developments in every facet of naval aviation. In addition, the coverage of fleet operations and the human interest articles on the noteworthy feats and accomplishments of individuals make the Naval Aviation News an entertaining as well as an informational periodical.

Crossfeed

Crossfeeds are "Official Use Only" publications issued by the Naval Safety Center. Each Crossfeed is in the form of a letter to the squadron aviation safety officer.

Crossfeeds often contain material extracted from Aircraft Accident Reports and reports from special investigations; therefore, they are not available for general distribution throughout an activity.

Generally, information concerning Maintenance Crossfeeds and General Crossfeeds will be passed on by the safety officer to those with an obvious need to know.

MICROFILM READER PRINTER

A relatively new concept in supplying maintenance activities with certain types of technical data has been accomplished by the use of microfilm. Microfilming is the photographic art of reproduction of text or pictures at ratios of reduction too great for reading or viewing without optical assistance. Microfilm is available as 16mm and 35mm filmstrip, mounted in individual frames on aperture cards and in cartridge form. A reader or some type of projector is required in order to enlarge the microfilm for reading.

The latest approach in this field has provided Intermediate maintenance activities with a microfilm reader printer which, as its name implies, enlarges the microfilm for reading or viewing and also has the capability of printing a permanent copy in a matter of a few seconds.

The quality assurance division, in conjunction with maintaining the technical library, is responsible for maintaining the reader printer. Therefore, the senior AZ assigned to the aeronautic technical library in an Intermediate maintenance activity may be concerned with the operation of the reader printer.

There are many different makes and models of microfilm readers and reader printers. Some have printing capabilities while others do not. Discussion of the operation of all the various models is not appropriate for this training course. The particular model discussed is widely used in the Navy.

14329

The Filmac 400C cartridge reader printer (fig. 6-1), manufactured by the Minnesota Mining and Manufacturing Company, provides a fast means of viewing 16mm cartridge microfilm and also prints a copy of the frame being viewed in a matter of seconds. This particular model is practically automatic; therefore, very little training is required to properly operate and maintain it. Like any delicate machine, the operating instructions provided by the manufacturer should be closely followed and the machine should not be abused.

As of this writing, the 400C reader printer is used primarily in the Component Repair Program; however, it is very possible that its usage will encompass other areas in the Naval Aircraft Maintenance Program. Cartridge sets of component repair data are provided to Intermediate level maintenance activities by NATSF. Subsequent updated microfilm cartridge sets are mailed to each user. Upon receiving updated cartridges, the user activity returns the outdated cartridges to NATSF for updating and reuse. Affixed to each cartridge is a label or index which provides information on the contents of that particular cartridge.

The 400C reader printer operates on standard 110-volt alternating current. It is controlled by an ON-OFF switch located above the viewing screen on the front of the machine. This switch controls the projection lamp, which illuminates the viewing screen and also the cooling blower.

This machine incorporates an automatic microfilm threading process; therefore, loading and threading microfilm is a simple task. Loading a cartridge of microfilm into the machine consists of inserting the cartridge into the holder with the open end toward the right. The cartridge is then pressed flat against the holder until the cartridge lock clicks. Threading is accomplished by turning the speed control knob counterclockwise and depressing the thread lever for approximately 2 seconds, or until images appear on the viewing screen. Microfilm advancement is stopped by returning the speed control knob to the center position.

AZ.25

Figure 6-1.—Microfilm reader printer.

14330

A counter registers the frames or images as they advance; therefore, by referring to the indexed cartridge, the approximate location of a frame can be determined and the microfilm rapidly advanced until this frame number corresponds to the counter reading. Rapid advancement of the microfilm is accomplished by turning the speed control knob counterclockwise—the farther the knob is turned, the faster the microfilm advances. The microfilm is wound back into the cartridge by turning the speed control knob clockwise.

Scanning a cartridge of microfilm in search of a specific frame can be accomplished by two different ways. One way is by the use of the handwheel located on the right-hand side of the reader printer. The other way is by use of the appropriate scan button. An arrow on each of the two scan buttons indicates the direction of microfilm travel. Once the desired frame is on the viewing screen, the focus ring is used to bring the image into sharp focus.

To make a print or copy of the frame of microfilm being viewed is a simple process. First of all, the image on the viewing screen should be centered and in proper focus. This can be accomplished by use of the handwheel and focus ring. Next, the exposure control knob must be set for proper exposure.

NOTE: Lower exposure control knob settings give light prints, and higher settings give dark prints. Experience with the reader printer will, for the most part, provide the operator with the setting to be used on the exposure control knob.

The print button is then pressed momentarily and the print comes out the print exit slot.

Prior to microfilm cartridge removal, the speed control knob should be rotated clockwise until all microfilm is wound back into the cartridge. To remove the cartridge, simply push back on the cartridge lock and remove the cartridge from the holder.

This reader printer uses a special type of copy paper and will not operate when the supply of copy paper is exhausted. It also uses an activator solution in the printing process. Under normal use, a bottle of activator solution is adequate for one roll of copy paper. It is a good practice to install a new bottle of activator solution each time a new roll of copy paper is installed. Th operator's instructions manual provided by the manufacturer gives complete details for loading both copy paper and activator solution. In addition, this manual gives instructions for routine cleaning and maintenance that can be performed by the operator.

TECHNICAL LIBRARY MANAGEMENT

As the Navy has become more and more dependent upon complex equipment, the need for technical information of all kinds has become more pressing. Aircraft maintenance activities cannot function properly without a considerable collection of technical reference material. While technical publications in smaller Organizational maintenance activities are not required on the same scale as larger Intermediate and Depot level activities, they are of sufficient importance that the squadron quality assurance division must maintain a fairly extensive library.

The aeronautic technical library is the central control point within aircraft maintenance activities which issures that the following requirements are met:

1. The full allowance of publications is on board.
2. They are readily available.
3. They are maintained current and up to date.
4. Security provisions are observed.

Senior Aviation Maintenance Administrationmen are frequently assigned duties as supervisors of technical libraries. In size, the libraries range from the small collections maintained by one part-time person to large libraries serving an aircraft maintenance department of a shore station. Any AZ may be called upon to set up a small library, or to revitalize an existing one which is not meeting the needs for which it was established. As personnel who work with technical material, they should know the basic principles of technical library maintenance whether or not they ever operate a large library.

A librarian must be a person who can assess needs for material and find means of acquiring and storing it. He must have an inquiring mind, be able to think constructively without following a blueprint, and be able to maintain balance in his operation. He must realize that the value of a technical library cannot be judged on the basis of how it compares in size with another library, but only on how well it meets the needs of the activity. A library expanded to provide an "empire," or one which grows indefinitely because the librarian feels he must maintain every item, is very bad and should be reduced to practical size.

14331

ORGANIZATION

Like other military units, the technical libary organization chart must make provision for responsibility and authority. Beyond this requirement, the organizational arrangements depend upon the size and function of the library.

An officer is usually designated, either by the department head or the commanding officer, as being in charge of the library. In most cases this will be the Quality Assurance Officer, and this duty is collateral to his primary duties. He determines the policies of operation and accepts responsibility for whatever classified material is maintained.

If the library is large enough to require the fulltime services of more than one enlisted person, the senior is designated as librarian, and is in charge of operating the library according to the policies established by the officer in charge. Publication clerks may be assigned as necessary to assist with the routine work.

PUBLICATIONS TO BE MAINTAINED

A few years ago, one may have been perfectly accurate in defining a library as a collection of books maintained in an orderly system, and a technical library as a collection of technical books. These definitions are now as obsolete as the saying that "what goes up must come down."

Large general libraries are likely to contain not only books, but films, tapes, prints, recorded music and books; as cultural repositories, libraries store information in whatever form is best suited to the material. Technical libraries have adopted this broader concept of a library, and have several different methods of storing the technical information needed by the users. A large technical library may include publications issued by many different government agencies, trade magazines and journals, microfilm files, commercially produced textbooks, and perhaps slides and filmstrips as well. It might, conceivably, contain a file of coded instruction tapes used to direct automatic machines in producing complex shapes or parts.

Before a librarian can get down to particulars and decide what he needs to keep in the library, there are two things he must determine: who will use the library and the nature of their work. These two factors will determine the range of the library by restricting the area to be covered. It is then a fairly simple matter to arrive at the individual publications to be procured.

As is the case of most technical libraries maintained in aircraft maintenance departments, they are used by maintenance personnel whose primary duties are repairing aircraft, and the publications required are those dealing with the details of repairing the applicable aircraft and all their component equipments, together with such catalogs as are needed to identify parts.

In most cases, the senior AZ will be responsible for the supervision of an established library and the bulk of the technical material will already be on hand. It might be well to review how these publications were received.

Newly commissioned and reactivated activities receive an initial outfitting of general publications automatically. They also automatically receive an outfitting allowance consisting of publications applicable to a particular model of aircraft. Revised publications were received by automatic distribution by use of Mailing List Requests for Aeronautic Publications. Still others were received by individual order on a one-time basis.

The Naval Aeronautic Publications Index provides valuable information for determining the various technical material required in aeronautic technical libraries. For example, the available technical manuals for a particular aircraft series can be found by using NavAir 00-500B. Likewise, the available letter type technical directives for a particular aircraft model are listed in NavAir 00-500C.

The various work center supervisors are another aid in determining technical information requirements. They should be consulted periodically to see if they have requirements for new or additional technical material. NavSup Publication 2002, Section VIII, Parts C and D, with its current supplement, should be reviewed regularly, as it provides a listing of new and revised publications as well as those canceled and superseded.

The quantity of publications required will depend on the size of the organization, number and location of work centers, number and different types of aircraft supported or maintained, etc. In any case, there should be sufficient quantities to meet the needs of the particular activity concerned. It should be kept in mind that all copies on hand must be maintained current, which requires considerable time; therefore, requests for publications should be

14332

14332

carefully screened and it should be ascertained that they are required.

The optimum size and range for a technical library are therefore directly dependent upon the size and mission of the technical group using the library. The library should contain all of the technical information needed by the activities served, in whatever form or format is best suited for storing that particular kind of information.

TECHNICAL DATA PROCUREMENT

As has been previously mentioned, there are several different channels and methods for procuring material for a technical library. Most of the publications are available at no cost to local operating budgets. Commercially printed books, trade or technical magazines, and some material printed by the Government Printing Office must be paid for.

The majority of the technical publications required are published by direction of the Commander, NavAirSysCom. All of these publications are available at the aeronautic publications stock point, listed in front of the current NavSup Publication 2002, Section VIII, Part C; however, most publications received will be by automatic distribution through the use of NavWeps Form 5605/2. It should be remembered that Form 5605/2 provides for automatic distribution of revisions and changes to existing publications. If additional or different publications are required, they must be ordered separately on appropriate requisition documents, and a new Form 5605/2 must be completed and submitted to NATSF in order to automatically receive revisions and changes to any additional publications. The newly submitted Form 5605/2 will automatically supersede any previous form on file in NATSF in its entirety; therefore, it must include all publications desired on automatic distribution.

A recent change in the method of ordering individual NavAirSysCom manual publications on a one-time basis is by the use of a Single Line Item Requisition Document, DD Form 1348 (Series). This requisition document is prepared and submitted through the local supply channels. This form requires a stock number to be entered in the appropriate space. Stock numbers for manual publications are listed opposite the publication code in NavSup Publication 2002, Section VIII, Part C. Letter type technical directives listed in NavSup Publication 2002, Section VIII, Part D, should be ordered by title and number on the Requisition and Invoice/Shipping Document, DD Form 1149.

Although Interim Changes and Bulletins are listed in NavSup Publication 2002, Section VIII, Part D, they are not available for issue through the Publications Supply System. They are listed only for informational purposes.

In addition to the NavAirSysCom, other systems commands publish a variety of material which may be useful. There is no hard and fast rule for procurement of this material. If the item desired is not listed in the cognizance symbol I catalog and no other source is known, send the request by letter directly to the publishing command.

Fleet and type commanders publish a limited amount of material, normally relating to operational problems in their respective areas. This material is usually supplied automatically to activities on the standard mailing list. If other requirements exist, a letter request may be submitted to the applicable fleet or type commander.

Situations may arise in both Organizational and Intermediate levels of maintenance which require the use of engineering drawings. Technical information of this type is normally supplied to these levels of maintenance in the form of microfilm reproductions of the actual drawings. Engineering drawing reproductions provide all the necessary information to construct, assemble, and install a part or an assembly. Aircraft and equipment manufacturers provide NATSF and Naval Air Rework Facilities with engineering drawings for use by engineering and repair personnel. These activities are also provided with microfilm and Vandyke (blueprint) copies of engineering drawings. As previously discussed, some type of optical assistance is required to view microfilm; therefore, these activities have microfilm readers and reader printers for viewing and reproducing copies of the drawings.

For the most part, microfilm copies of engineering drawings are provided in filmstrip and in single frames mounted on aperture cards. Aperture cards are standard size EAM cards and have printed and keypunched identifying information concerning the frame of microfilm which they contain. It is conceivable that reproductions of engineering drawings may, in the future, be provided in cartridge form for use by the Filmac 400C reader printer previously discussed.

The senior AZ, supervising the operation of a technical library in an Organizational or Intermediate activity, may be required to procure

14333

microfilm. Naturally, microfilm would be of little or no value to maintenance personnel unless there is some type of reader available for viewing it.

Most aircraft and equipment IPB's contain manufacturer's engineering drawing numbers for various components. If microfilm of a particular drawing is required and the drawing number unknown, then the aircraft or equipment company technical representative should be consulted for this information.

In most cases the requirement for microfilm will be on an as-needed basis; therefore, large stocks will normally be maintained in the technical library of Organizational and Intermediate activities. The various work center supervisors will normally notify the person in charge of the technical library of their requirement for microfilm.

All requests for microfilm of engineering drawings should be forwarded to the Commanding Officer, U.S. Naval Air Technical Services Facility (EDD), 700 Robbins Avenue, Philadelphia, Pennsylvania 19111, on a DD Form 1149. When a complete set of drawings for an aircraft or equipment is requested, the individual drawings need not be listed; however, the request must be accompanied with a statement of justification. Requests for classified and unclassified drawings must be submitted on separate forms.

A file copy of each request should be maintained by the requesting activity as well as any correspondence relating to the request. Since approximately four and a half million drawings are available from NATSF, proper submission of requests for copies of these drawings is essential to avoid delay in receipt.

MAINTAINING PUBLICATIONS

A technical library may be filled with hundreds of volumes of interesting, important information; but if they cannot be located quickly, or are not current, they are of little use to anyone. There must be systematic filing and cross-referencing so that each item can be located. There must also be a constant program to keep every publication current.

All technical data received in the library should be promptly screened so that routing to appropriate divisions and branches can be accomplished. Naturally, material of an urgent nature should have priority over routine publications. The screening and the routing of technical publications are closely related to that of correspondence, discussed in chapter 3 of this training course. It should be kept in mind that the main reason for prompt screening and routing is to get the technical data in the correct hands so appropriate action, when required, can be taken. Should difficulties be encountered while screening technical publications, quality assurance division personnel should be consulted.

After screening and prior to routing the publication, a Catalog Card, OpNav Form 5070-11, should be prepared for the custody record file. The publication should also be marked with some identifying mark (preferable a rubber stamp) on the front cover and title page. Each publication should also contain a number. For example, if two copies of a particular publication are received or maintained, they would be numbered 1 and 2, respectively. Each time a publication is checked out the person to whom it is issued signs the Catalog Card. This system provides quick reference as to who has a particular publication in case it is needed. When the publication is returned, the librarian signs the card in the drawee's presence to show its return.

Sometimes, due to the size of the activity, location of divisions and branches, and type of publications concerned, it is not feasible for them to be routed. In this case the librarian may route a listing containing the titles of all new publications to inform all concerned of the new publications available in the technical library.

When changes are received, they should be entered in the appropriate publications as soon as possible. For those publications in the library, the changes must be entered by library personnel. For those publications checked out, deliver the changes to the holders of the publications along with a Change Entry Certification. The holder is responsible for entering the change and informs the librarian to this effect by signing the certification and returning it to the library, where it is filed.

An AZ who is familiar with the principles and uses of locator systems should have no difficulty establishing a workable system for a technical library. He should keep in mind that the library is much more likely to grow than to dwindle, and should use a locator system which can allow expansion without extensive changes.

14334

The locator file should be in two parts, one part alphabetical and the other numerical. The alphabetical file should include titles, major subject divisions, and authors if applicable, each on separate cards. Publications which are assigned numbers by the originating activity should also be listed under those numbers in the numerical section of the file. Every item in the library should be represented by at least one entry in the file, and many will require several reference cards. Such a file will require a little more work to set up, but the time saved in locating material will more than compensate for it.

Numbered shelves and a good locator file will make it unnecessary to shift everything in the library to add a few new volumes. By the very nature of the material, there will be many changes in library content. A system requiring constant reshuffling to make room for new material will likely break down from the amount of work required. A system based on arbitrary locations discourages casual browsing, but will allow new volumes to be placed in vacant spots in the shelves, regardless of where they occur. It is the same principle which applies to storing material; instead of spare parts, information is stored.

Except for the time involved, there is no particular problem in keeping technical publications current and up to date. If the library is on a mailing list, many of the changes are received automatically as they are issued. It is a simple matter to compare the dates given in the publications index with the dates on the numerical index cards, if these latter are annotated as changes are made.

To insure that a NavAirSysCom manual type publication is current, the date or latest revision date shown on the manual should be compared with the date listed opposite the manual title in NavSup Publication 2002, Section VIII, Part C, and its current supplement.

Publications issued by other activities are not so easily checked. If the publishing offices issue annual listings of current publications, these should be compared with publications maintained locally. Commercially published material, usually bound in hard covers, is not ordinarily revised annually and will be little trouble in this respect.

WORK CENTER PUBLICATIONS

All publications maintained by the technical library are not kept in the library. Production personnel require the regular use of technical publications; therefore, some of them should be readily available in the various work centers throughout the maintenance activity. This means that several volumes of the same manual may be required in a single maintenance activity. It is not feasible for each work center to have an individual copy of every publication that is used by the particular work center; however, they should have the publications most often used. These should include publications such as applicable volumes of the Maintenance Instructions Manual, Illustrated Parts Breakdown, and certain general manuals. The work centers also have requirements for some letter type technical directives. Regardless of the technical publications kept in the work centers, all should be checked out from the technical library. Catalog Cards, maintained in the library, should show the holders and location of all checked out publications. By using this system, the technical library maintains control of all work center publications and applicable revisions, and changes can be procured as necessary to keep these publications current.

The fact that a particular publication is kept in a work center does not mean that only one copy is required in the activity. A current copy of all technical publications required in the work centers should be maintained in the library.

It is the responsibility of the technical library supervisor to insure that the publications required and kept in work centers are current, as well as those kept in the library. When changes for a particular publication are received, it is a simple task to check the Catalog Card and find the location of the publication. If it is checked out, the change, together with a Change Entry Certification, should be forwarded to the holder for incorporation. Upon incorporation of the change, the certification is completed by the holder and returned to the library. This provides a record that the change has been incorporated in the applicable publication. It is suggested that a system be devised whereby there is a time limit for incorporation of changes. This would discourage the normal habit of "putting off" the incorporation. Numerous noncurrent publications have been used in completing maintenance tasks due to the fact that someone "put off" the incorporation of a change. Situations like this are a potential flight safety hazard and indicate substandard library supervision.

14335

Periodic spot checks of each work center's publications should be made to ascertain that the publications are being updated properly. Although this may appear to be a difficult task, it is actually a simple process. One method is by checking the changed or revised date of the publication against the Catalog Card, which should have all applicable change or revision dates listed.

Further spot checking is accomplished by the use of the List of Changed Pages, located in the publication. This list is on the back of the title page of the latest revision and should be the first page of the manual. It is identified by the letter A. Necessary additional pages are lettered B, C, etc. This list includes the number of each page changed/revised since the last basic issue of the manual plus the date it was changed/revised. Several changed/revised page numbers from this list should be selected and checked. The date on the bottom of those pages checked should correspond with those listed on the A page.

NOTE: That portion of the text affected by the current change or revision is normally indicated by a heavy vertical line in the outer margin of the page.

To check manuals which are updated by interim changes, it is necessary to compare the interim changes listed on the Catalog Card with those entered on the Flyleaf of the Interim Manual Change Summary of the manual.

REPORTING ERRORS IN TECHNICAL PUBLICATIONS

The NavAirSysCom has provided procedures for reporting of omissions and errors in aircraft and equipment technical publications, test tapes, and check lists. Discrepancies in the following technical manuals are reported using these established procedures:

1. Service Instructions Manuals.
2. Overhaul Instructions Manuals.
3. Maintenance Instructions Manuals.
4. Structural Repair Manuals.
5. Illustrated Parts Breakdown.
6. Periodic Maintenance Requirements Manuals, Maintenance Requirements Cards, and related Sequence Control Charts.

The report is prepared on the Unsatisfactory Material/Conditon Report (UR), NavAir Form 13070/5. The UR form is a four-page carbon interleafed set. Detailed instructions for preparing and submittal of the UR are printed on the cover of each set.

The original of the UR is forwarded to NATSF and a file copy should be retained by the originating activity for record purposes. The third (tag) copy is not required for this type of reporting.

The UR form is also used for submittal of specific information concerning failures, material defects, and other critical situations affecting naval aeronautic equipment which require prompt attention and corrective action. This includes hazards to flight safety and aeronautic equipment found discrepant as a result of design deficiency, faulty manufacture, faulty overhaul, or faulty preservation/packing.

SECURITY OF CLASSIFIED PUBLICATIONS

The problem of security of classified publications in the technical library is generally limited to ways and means of storing, using, accounting for, and disposing of such publications in accordance with existing directives. The basic Navy security directive relating to the safeguarding of classified information is the Department of the Navy Security Manual for Classified Information, OpNav Instruction 5510.1 (Series). Its provisions apply to all activities of the Navy. The application of security measures regarding technical library classified publications may be further influenced by locally issued directives which supplement the basic directives.

All personnel in the Navy are individually responsible for assuring that knowledge of classified information which they prepare or handle is made available only to persons who have clearly established a legitimate "need to know." Classified material is procured for the technical library because it is needed during the performance of some maintenance functions. Use of these publications by maintenance personnel should be anticipated and steps taken to procure security clearances for selected personnel most likely to require the information.

The technical library supervisor must initiate procedures that insure him positive control of all classified publications for which he is custodian. The first problem of custody is storage. Classified material may not be kept on

14336

open shelves accessible to unauthorized personnel. While large libraries sometimes need walk-in safes for classified material, most find that a few locking drawer files are adequate. The Navy Security Manual discusses storage containers of varying degrees of integrity. Also provided in the manual are specific requirements for safeguarding combinations and keys for locks, as these, to various extent, affect the protective capabilities of the different types of containers.

Classified publications which are no longer required in the library should be disposed of by approved methods.

Publications listed in NavSup Publication 2002, Section VIII, Parts C and D, are unclassified unless otherwise marked "1" (confidential) in the column headed "SC." The numerical Index is not classification authority. The supplements to the index contain information of classification action on a "when-occurring" basis.

14338 14337

- Conduct a discussion on the factors to be considered before making alterations. Consider such aspects as fabric characteristics, seam allowances, darts, extent of alterations needed, time involved in making alteration, and effect of alteration on garment design.

- Show trainees the importance of retaining the grain line of various garment sections by using striped or plaid clothing on dressmaker's dummies. The dummies should be padded to create figure problems such as large hips, low bust, rounded shoulders, large abdomen, and short waist. See Appendix I. Use a pattern piece on an opaque projector to show how the garment part would be altered. Demonstrate the alteration on a readymade garment. See Appendix J.

- Demonstrate how garments are pinfitted and how markings are transferred to the wrong side of fabric. Have trainees practice these techniques.

- Invite a resource person to demonstrate methods for lengthening and shortening sleeves and skirt hems, changing waist and shoulder lines, altering bust darts and side seams, replacing zippers, and changing sleeve caps.

- Have trainees suggest solutions to alteration problems on many different types of garments and fabrics. Use padded dummies and/or class members for models.

- Have a committee make a survey of the types of alterations most often made on men's clothing. Analyze the list for competencies of class members and demonstrate unfamiliar procedures.

- Use slides or photographs to illustrate correct and incorrect fit of men's garments. Invite a person from a men's tailoring shop to discuss standards for proper fit of clothing and to demonstrate the basic alterations that are usually required.

- Have each trainee bring to class a pair of discarded men's trousers for practice in making such alterations as replacing a zipper, altering the waistline and crotch, replacing one pocket, replacing the tip of other pocket, cuffing one leg using marker, and cuffing other leg using formula.

- Have trainees make a reference notebook of procedures commonly used in alterations. Include such techniques as changing dart angles and hem lines, fitting slacks, correcting faulty necklines, and cuffing pants. See Appendix J.

- Plan a field trip to a place specializing in leather, suede, and fur garments. Ask alteration person to demonstrate procedures used in making alterations on these fabrics. Have trainees record procedures in their reference notebooks.

- Role play a series of customer-fitter situations which show interaction between customer and fitter. Have class note and discuss good and poor techniques used by fitter. See Appendix K.

Chapter 7

MATERIAL CONTROL

It has been said that "the only permanent thing in the supply field is change." This statement may be slightly exaggerated, but it is quite true at times. The important thing to remember is that changes in supply procedures are necessary to keep pace with the changing maintenance concepts of the modern Navy weapon systems. New systems are constantly under development to insure that supplies and materials are available in the right quantities, at the right place, and at the right time for the end user.

One of the functions of the senior AZ in a maintenance activity is to coordinate the material support for the worker actually performing maintenance tasks. To accomplish this function the AZ must have a working knowledge of the Navy supply system and its application to the maintenance of aircraft. It is also a responsibility of the senior Aviation Maintenance Administrationman to insure proper utilization of materials within his particular area of responsibility.

AVIATION SUPPLY

As Aviation Maintenance Administrationmen advance to first class and chief and occupy supervisory billets, they will become more involved in the details of rendering support for the man on the job. One of these detail areas is in the field of aviation supply.

Aviation supply personnel are vital members of the aircraft maintenance team; and the AZ, as well as the other aviation maintenance ratings, must work in close harmony with them if successful teamwork is to be achieved. The team must work so that a flow of materials is maintained from the manufacturer throughout the fleet. Although the AZ may not use parts and components as do some of the other maintenance ratings, a correct concept of supply's relationship to the entire organization is essential in the supervision of all aircraft maintenance functions.

The primary objective of the Navy supply system is to achieve a proper balance between the supply of materials and the material requirements of the Department of the Navy. The aviation supply system is designed to achieve this objective for the aeronautical material segment. It must be emphasized at this point that the aviation supply system is not separate and distinct, but is a segment of the integrated Navy supply system. The procedures and organization in this chapter are appropriate for the aviation segment, and in many instances are equally appropriate to other segments of the Navy supply system.

ORGANIZATION AND FUNCTION

The command exercising management control over the policies and procedures of the aviation supply organization is the Naval Supply Systems Command. The Commander, Naval Supply Systems Command is usually a rear admiral who is appointed by the President with the advice and consent of the Senate. He works with the delegated authority of the Secretary of the Navy, and all policies and procedures of the aviation supply organization emanating from him have the full force and effect of SecNav orders.

To better understand the relationship of the Naval Supply Systems Command to the aviation supply system, it might be well to quickly review the development of the Navy supply system.

Prior to 1842 the commanding officers of ships and stations were responsible for the procurement of their own supplies. They were furnished funds for this purpose by the Navy Department and were required to account for

14338

all expenditures. In addition to creating an intolerable burden of paperwork on the Navy Department, this procedure had the effect of forcing prices upward, especially when two commanding officers were bidding for some scare commodity.

In 1842 Congress approved the establishment of a Bureau of the Navy to take cognizance over all matters of naval supply. The primary responsibilities of this infant supply bureau were the procurement, maintenance of custody, and issuance of naval material. They are the primary responsibilities of the Naval Supply Systems Command today. Every function of the Naval Supply Systems Command is directly related to one or more of these responsibility areas.

In the early years of naval aviation when the Navy had few aircraft, the procurement of spare parts was much like the old system whereby commanding officers dealt directly with the sellers to fill the needs of each command. The pioneer naval aviation project directors had to deal directly with the manufacturers as parts were required.

By 1917 the Naval Aircraft Factory (NAF) in Philadelphia had come into existence and was assigned responsibility for the procuring of aircraft and spare parts. Other responsibilities assumed by NAF included the repair of aircraft, the manufacture of some spare parts, and eventually the manufacture of complete aircraft. There may still be a few aviators around today who earned their Navy wings in the old N3N, built by NAF.

In 1921 the Bureau of Aeronautics (BuAer) came into being and assumed the responsibility of procuring aircraft and aircraft engines. The responsibility for procuring spare parts and other aeronautical material remained with NAF, which until 1941 was the aviation supply center of the Navy.

The Aviation Supply Office (ASO) was established in 1941 under the technical control of BuAer and the management control of the Bureau of Supplies and Accounts. The function of ASO was the procurement, custody, and issuance of aeronautical spare parts and technical material. This is essentially the function of ASO today under the technical control of the Naval Air Systems Command. Management control of ASO is exercised by the Naval Supply Systems Command.

RESPONSIBILITIES OF THE NAVAL SUPPLY SYSTEMS COMMAND

The general functions of the Naval Supply Systems Command include many that are not related to aircraft maintenance, and not of primary interest to AZ personnel. Listed below are some of the more important general functions of the Naval Supply Systems Command:

1. Supervises the procurement, receipt, custody, warehousing, and issuance of Navy supplies and materials, exclusive of ammunition, projectiles, mines, explosives, and medical supplies.
2. Supervises and directs the operation of the supply phases of the Navy supply system and administers the redistribution program of excess personal property within the Department of Defense and the sale of Navy surplus property.
3. Authorizes and supervises the transportation of Navy property.
4. Prepares budget estimates and administers funds for the supply distribution system.
5. Renders an annual report to the Congress of money value of supplies on hand at the various stations at the beginning of each fiscal year, the disposition thereof, purchase and expenditure of supplies for the year, and balance on hand.
6. Coordinates the compilation and arranges for the printing of the Catalogs of Navy Material.

Some additional functions of the Navy Supply Systems Command that are of interest to AZ personnel are the general functions of ASO. These include the following:

1. Responsibility for overall determination of requirements, procurement, and distribution of standard aeronautical materials. (Certain materials excepted; such as complete aircraft and engines, complete electronic equipment, major photo equipment, nonstandard and experimental aerological equipment, and items of naval weapons ordnance equipment.)
2. Maintenance of a complete file of ASO and Naval Air Systems Command contracts, letters of intent, amendments, extensions, and change orders, and distribution of all necessary copies of documents to Navy field activities.
3. Stock control of aeronautical materials at all aviation supply facilities, including control of packing, preservation and distribution of material under ASO cognizance to, from, and between aviation supply facilities and major supply points.

OFFICIAL

14339

4. Maintenance of complete records of material on order and followup procedure necessary to effect timely deliveries for all material under ASO cognizance.

5. Maintenance of up-to-date records of existing storage facilities at depots, major supply points, and operating stations for aeronautical materials, and control of influx of materials in aviation supply channels so as not to exceed existing storage facilities.

6. Determination and disposition of obsolete and excess aeronautical material under NavAirSysCom cognizance.

7. Preparation and distribution of the Navy Stock List of ASO, including interchangeability data.

8. Compilation and distribution of some allowance lists subject to approval by NavAirSysCom.

9. Compilation of lists of spare parts to be salvaged from surveyed aircraft.

10. Followup on delivery, stock recording, reallocating as necessary, and distributing change material promulgated by NavAirSysCom.

11. Establishment and maintenance of a statistical unit which assembles, compiles, and analyzes usage data.

12. Maintenance of a representative at each aircraft manufacturer's plant who keeps ASO fully informed, as requested, as to all changes which affect spare parts under procurement.

13. Establishment of an inspection service which inspects aviation supply activities within established naval districts.

APPROPRIATIONS

At one time or another, almost everyone has had the frustrating experience of not being able to draw from supply some item needed immediately; the usual reason given being, "We do not have any money left." It takes only a short time to realize that the Navy does not operate with unlimited funds. This section and the following section, titled "Operating Budgets," are presented to further an understanding of the system whereby funds are made available at the user activity level for operating expenses.

The main money pool of the government is the General Fund of the Treasury. Funds come into the General Fund from such sources as income taxes, excise taxes, import-export taxes, etc. The only way for money to be expended from the General Fund is by congressional action, which has to be approved by the President. A bill passed by Congress which includes the expenditure of funds from the General Fund is called an appropriation.

An estimate of the amount of money required for the operation of the Defense Department during a given fiscal year is prepared by Department of Defense fiscal experts well in advance of the beginning of the fiscal year. The Congress studies the proposed budget in the light of world affairs, the current domestic economy, and such other considerations as they see fit, then acts upon it. Congress may increase the amount requested, decrease it, or pass it as is. After presidential action is completed, the money is made available to the Department of Defense to be spent during a specified year. This is known as an "annual" or "one-year" appropriation.

Congress and the President may also approve "no-year" appropriations for special projects such as large construction programs over an unspecified length of time.

Another form of appropriation is the "multipleyear" appropriation for projects which will be completed in a predictable length of time. An example of the use of this type of appropriation is the money appropriated to cover the expenses of the NROTC college programs for the next 4 years.

The appropriation by which the AZ is most affected is the "current-year" appropriation. After the appropriation or expenditure authorization is received in the Department of Defense, it is prorated among the services as a percentage of their previously submitted budget estimates. The Navy's share is prorated among the various systems commands and bureaus in essentially the same manner; that is, as a percentage of their estimated requirements for the coming fiscal year. The money to be spent for naval aviation is made available to NavAirSysCom. Here, part of the money is allocated to ASO for the purchase of aircraft spare parts and related equipment in quantities which past usage data has indicated will probably be sufficient for the coming year. These spare parts are furnished to the operating activities at no cost, since their usage has been anticipated and the items paid for in advance. The account from which money was spent to buy these items is known as the Appropriation Purchase Account (APA). Material received in the user activities from this account is known as APA material.

Another part of NavAirSysCom funds is made available to the operating activities in the form of operating budgets.

OPERATING BUDGETS

Funds available within a appropriation account for commitments, obligations, and expenditures are administered through the issuance of operating budgets. An approved operating budget is an authorization granted for the purpose of incurring commitments, obligations, and expenditures to accomplish the mission of an activity. Therefore, an approved operating budget is a subdivision of an appropriation which provides the funding authority for an official to accomplish a specific function or mission.

Approved operating budgets concerning naval aviation are authorizations by NavAirSysCom to the user activities to spend a certain amount of money during a given length of time for specified purposes. User activities are shore commands, which operate aircraft, and the major air type commanders.

Operating funds for stations, rework activities, etc., concerned with the operation and maintenance of aircraft and related equipment are allotted to them by the NavAirSysCom as an operating budget. Departments within these organizations normally submit their department budget to the station comptroller who reviews and combines the different department budgets into a recommended station budget. Senior AZ's may be called upon to assist in furnishing a realistic estimate of division operating expenses and future needs which the department head may use in formulating the department budget.

Since there is a relatively long period between budget submission and the subsequent receipt of funds, the necessity for accurate estimates of future requirements and strict management of materials for which allotted funds are expended cannot be overemphasized.

Operating funds for squadrons and units are apportioned to them by their type commander as an Operating Target (OPTAR). Routine nonaviation expenses for operating squadrons and units are absorbed by the ship or station to which assigned.

Operating Targets

Funds to finance the operation of aircraft are allotted by the NavAirSysCom to the air type commanders. Operating funds for squadrons, units, and ships are apportioned to them by their cognizant air type commander as an operating target (OPTAR). An OPTAR is a planned estimate which the air type commander allocates for the financing of aircraft operating costs during a given period of time. OPTAR's are issued on a quarterly basis and unused funds from the previously issued OPTAR revert to the control of the type commander as each new OPTAR is authorized. Type commanders provide OPTAR's to squadrons, units, and ships under their operational control, whether or not the user activity is based ashore.

There are several different types of OPTAR's issued by air type commanders for aviation purposes. Two that are of interest to AZ personnel are flight operations and aircraft maintenance funds. These are discussed in the following paragraphs.

Flight operation funds are used primarily for the purpose of financing actual flight operations; therefore, they have application at the Organizational level. These funds finance the following:

1. Aviation fuels and lubricants consumed in aircraft.
2. Liquid oxygen.
3. Aerial film for use in aircraft cameras.
4. Flight clothing and operational equipment authorized in NavAirSysCom Allowance List (NavAir 00-35QH-2).
5. Flight deck safety shoes.
6. Squadron administrative consumable office supplies.
7. Unit identification marks (shoulder patches) for initial issue to newly reported personnel.
8. Material and services required when located at an activity without Navy or Marine Corps Intermediate maintenance capability.

Aircraft maintenance funds are provided to Organizational and Intermediate maintenance activities to finance the cost of various supplies and materials consumed in the performance of aviation maintenance. These funds finance the following:

1. Repair parts, common hardware, lubricants, cleaning agents, cutting compounds, metals, and other materials incorporated into or expended in the performance of aviation maintenance of aircraft, engines, aeronautical components and subassemblies, and Navy maintenance of aviation maintenance support equipment.

14341

2. Fuels and lubricants consumed by aircraft engines in the performance of complete section repairs.

3. Pre-expended, consumable maintenance material.

4. Replacement of expendable or consumable allowance list items with material accountability codes B and C. (Allowance list and material accountability codes are discussed later in this chapter.)

MATERIAL IDENTIFICATION

In addition to the task of supervising lower rated AZ personnel in the performance of routine duties, senior AZ's may be assigned maintenance supervisor duties. In most cases, these duties will encompass the task of assisting in the procurement of material and parts used by production personnel. One important area of material procurement is the correct identification of the material and parts required.

There may be times when a part or some technical material is needed and the stock number is unknown. At other times some material may be on hand and its identity not positively known. A knowledge of the various methods of identifying material other than by stock number will often help speed the completion of a maintenance task. Certain data may be available which do not identify an item but which may lead to positive identification. The following sections discuss some methods of identifying material.

FEDERAL STOCK NUMBERING SYSTEM

The Defense Cataloging Standardization Act, passed by Congress in 1952, provided for a uniform system of identification, classification, and stock numbering throughout the Department of Defense. Prior to this time there were many stock numbering systems within the Department of Defense and within the Navy itself. It was possible for the same item to be stocked under different stock numbers as Navy general stores, Navy aviation stores, Air Force stores, Army quartermaster stores, and many others. There was no cross-reference system whereby an agency could determine if its excess material was the same as that which was in short supply in another agency.

The federal cataloging system eliminated this situation by placing all like items under a federal stock number bearing a common official government name. This system was made applicable to all agencies within the Department of Defense.

Under the federal cataloging system, federal stock numbers are required for all items that are subject to central inventory management within the Department of Defense. Each Navy item to be stocked under centralized inventory control is assigned a federal stock number which is used in all supply management functions. This federal stock number is listed in supply publications in which the item is referenced.

The Federal Stock Numbering System was intended to create and improve standardization of items of military supply in servicewide use and reduce excess inventories which, for the most part, were caused by lack of standardization. Also, the reduction of excess inventories eliminates substantial financial loss due to material obsolescence.

Federal Stock Number (FSN)

The FSN is an 11-digit number which furnishes positive identification of virtually all items of supply from purchase to final disposition. The 11 digits are uniformly arranged in groups of 4, 3, and 4 digits, with groups separated by hyphens. The 11 digits are made up of a 4-digit federal supply class (FSC) and a 7-digit federal item identification number (FIIN). In addition to the 11-digit number, the Navy supply system utilizes certain code prefixes and suffixes to aid in the performance of various management functions. These codes are of significance only within the Navy and are not used during interservice transactions. When the prefixes and suffixes are used, the FSN is known as a coded FSN.

Figure 7-1 describes the format of a coded FSN, including applicable management codes for an item of supply under the cogniznace of ASO.

The following paragraphs discuss the various parts of a coded FSN and frequent reference to figure 7-1 will assist in understanding the composition of coded FSN's.

A cognizance symbol consists of a 2-digit code prefixed to an FSN to identify and designate

14342

Figure 7-1.—Breakdown of a coded FSN.

the systems command, office, agency, or Navy inventory manager that exercises management control over specific categories of material. Although the cognizance smybol officially consists of two digits, it will be observed that publications and requisitioning procedures frequently drop the first digit for APA material, thus 2R is referred to as R, etc.

Listed in table 7-1 are some of the more common cognizance symbols, together with the type material controlled and the name of the cognizant command or office.

Material control codes divide inventories into segments reflecting similar demand, repairability or other characteristics. For example, some material control codes reflect either fast or slow moving demand characteristics while others denote whether the item is to be repaired by Intermediate or Depot level maintenance activities.

Material condition codes classify material in terms of readiness for issue and use, or to identify action underway to change the status of material. For example, one material condition code is used to indicate that a particular item is serviceable and ready for issue. If, after issue from the supply system and through use this item becomes unserviceable, its material condition code would be changed to reflect the requirement for rework, repair, etc. Naturally, upon completion of rework or repair the material condition code would be changed to show that the item is serviceable and ready for issue. Therefore, this code changes from time to time on a particular item depending on the condition of the material.

The federal supply classification class is the first four digits of the FSN and is used to group related commodities together. Each item of supply is classified in one, and only one, 4-digit FSC. The first two digits denote the group or major division of commodities, and the last two digits denote the class or subdivision of commodities within a group. Aircraft components and accessories are in group 16, therefore, in the FSC 1630 the 16 denotes an aircraft component or accessory and the 30 indicates a particular class within this group, which is aircraft wheel and brake systems. Other classes in group 16 are indicated as 1610—propellers, 1620—landing gear components, etc.

The federal item identification number consists of the last seven digits of the FSN. It serves to differentiate each individual item of supply from all other items of supply; that is, each individual item of supply (F-4B brake, P-3A brake; etc.) is assigned a separate FIIN. The FIIN in no way determines the position or sequence of the item in relation to other items.

The technical supply management code (TSMC) is a four-character code suffixing the FSN. As previously discussed, the FSC class classifies material by what it is. The TSMC groups material by associating supporting spare parts with their end assemblies.

NOTE: A recent change has replaced the four-character TSMC with a two-letter special material identification code (SMIC). However, like many areas where changes are made, a certain time element is involved; therefore, the TSMC will still be used for sometime on many coded FSN's. A SMIC is a management code added as a suffix to an FSN to indicate a primary weapon support item, specialized material, or general/common material. ASO has published a conversion guide which cross references the SMIC with the TSMC.

14343

Table 7-1.—Cognizance symbols.

Symbol	Cognizant activity	Material controlled
1E	Aviation Supply Office	Photographic material
2R	Aviation Supply Office	Aeronautical equipment
2V	Naval Air Systems Command	Aeronautical equipment (certain items only)
1N	Electronics Supply Office	Electronic equipment
20	Naval Training Devices Center	Training devices
1W	Fuel Supply Office	Fuels, lubes, and gases
1I	Naval Supply Depot, Philadelphia	Forms
0I	Naval Supply Depot, Philadelphia	Publications

Many variations of coded stock numbers will be encountered in maintenance work. These variations indicate material management responsibilities for the item; flag certain items as recoverable, consumable, high value, etc.; and identify the condition of the material if it is not ready for issue.

Becaues the variety of codes is so extensive and the trend to single service management of items has caused so many changes in recent years, a list of codes that might be prefixed or suffixed to a stock number would not be appropriate for this course. The primary things to keep in mind are that the basic stock number, consisting of three groups of numerals, identifies the item from a technical point of view and that the other codes identify material management characteristics.

STANDARDIZATION OF ITEM NOMENCLATURE

As part of the federal cataloging system, each item of supply is assigned an official government name. Maintenance personnel frequently refer to material by trade name or terminology other than the official government name. Alphabetical indexes in the various stock catalogs and other publications are sequenced by official name. To effectively utilize these publications, it is necessary to become acquainted with the proper nomenclature.

The assignment of names to stock items is practically as important as the assignment of FSN's. When items are inducted into the supply system, official government nomenclature must be assigned. Often this item name plus additional descriptive data will differ from names of items previously used. If difficulty is experienced in locating a familiar item in the catalog, it is quite possible that the name has been changed to conform to a more general usage. A few examples will show the importance of correct item nomenclature. It will be found that a "swab" is a small stick with a tiny wad of cotton on one end, and is used by the Medical Department. In order to clean the decks it will be necessary to think of another name for "swab." "Mops" will be found listed in the catalog, together with the correct FSN. Other examples are as follows; "Ceilometer" becomes "Projector, Cloud Height"; "Zipper" has become "Fastener, Slide Interlocking," etc.

NAVAL MATERIAL CATALOGS

Federal and naval material catalogs provide information necessary to identify and procure items of material for operation and maintenance of activities afloat and ashore. The catalog most commonly used by aviation personnel is the Federal Supply Catalog Navy Management Data List.

The Navy Management Data List (NMDL) consists of two separate sections. One section, the Fleet Ballistic Missile Weapons System Supplement, has application only to submarine forces and therefore is of little or no use to aviation maintenance personnel.

The other section, titled the Management Data List, includes basic management data necessary for preparing material requisitions. Also, it is the instrument for publishing data relative to stock number changes, unit of issue,

14344

unit price, shelf life of material, number of items contained in a package, and associated information.

The NMDL is designed to disseminate management type information as it relates to an FSN. It is not designed to act as a comprehensive catalog of material in the supply system, identify an item to an FSN, or serve as a shopping guide. Therefore, in order to get the necessary FSN or other needed information for making effective use of the NMDL, additional publications must be used in conjunction with the NMDL. These include the Deleted and Superseded FIIN List, the Consolidated Repairable Item List, and the Federal Supply Catalog Navy Master Cross Reference List.

The Deleted and Superseded FIIN List provides historical data of stock number deletions and supersessions. It should be remembered that the FIIN taken from this list is referred back to the NMDL for the requisitioning data.

The Consolidated Repairable Item List contains a listing of Navy managed mandatory turn-in repairable items. It is prepared to assist in identifying Navy managed mandatory turn-in repairable items and pertinent movement priority designators. Some repairable items under the cognizance of ASO and the NavAirSysCom are not included in this publication. These are listed in the ASO Master Repair List.

The Federal Supply Catalog Navy Master Cross Reference List provides the means of identifying an item from a reference number (part number, drawing number, etc.) to an FSN. The FSN found in this publication should be referenced back to the NMDL for all pertinent information required in requisitioning material.

IDENTIFICATION SOURCE DATA

As previously stated, positive identification of an item of supply has been accomplished when it is identified to its applicable FSN. For the most part, the FSN is not marked on material; however, most material has some type of data affixed to it that can be used for identification purposes. Certain data which do not identify an item but which aid in obtaining positive identification are discussed in the following paragraphs.

Manufacturer's Part Number

Normally, the manufacturers of parts stamp, etch, paint, or otherwise affix a part number on each item manufactured. The use of this manufacturer's part number and the knowledge of the part's application (that is, on what equipment it is used) normally lead to the positive identification of the part's nomenclature and FSN. The part number can be ascertained to be correct by reference to the appropriate Illustrated Parts Breakdown (IPB), and the FSN may be obtained by reference to the appropriate Federal and Naval Material Catalogs.

Drawing Number

A drawing number consists of letters, numbers, or a combination of both which are assigned to a particular drawing for identification purposes. The activity controlling the drawing (normally the manufacturer) assigns the number in conformance with their drawing number system. One drawing may apply to several items; thus, other distinguishing data may be necessary to identify the item on the drawing.

Drawing numbers may be used to identify the microfilm available in some technical libraries. Some large assemblies are illustrated in the appropriate Illustrated Parts Breakdown but are not broken down sufficiently to show identifying data for their component parts. By obtaining the drawing number of the larger item and cross-referencing it to the applicable microfilm, sufficient identifying information for the component part may be obtained.

Nameplates

Some aeronautical materials have nameplates attached which provide such information as the manufacturer's name or code, make or model number, serial number, size, voltage, phase, etc. Identification data taken from the nameplate of the old part can be very helpful in identifying and procuring a replacement. Nameplate data is particularly useful when requesting nonstandard material which is not subject to the federal cataloging system.

Markings and Measurements

Special coded markings, other than part numbers, and measurements often aid in the identification of some materials. For instance, compressed gas cylinders are color coded to identify the contents of the cylinders. Sheet metal is stamped with a significant identifying symbol which is repeated at intervals

014345

throughout the length of the sheet. This symbol includes the composition, temper, thickness, etc.

Flexible rubber hose is marked with a symbol which is repeated at intervals throughout the length of the hose. Bare wire is separated according to diameter. Tubing has two types of measurements—outside diameter, given in inches; and thickness of the wall, given in thousandths of an inch. Female fittings such as crosses, tees, and couplings are measured across the inside diameter of the threaded opening. The male fittings are measured across the outside diameter of the male threads.

Source Codes

Item Source Codes are symbols which indicate to a consumer a source of supply for an item required to maintain or repair aeronautical articles. Specifically, these codes indicate whether the item is to be requisitioned from the supply system; to be manufactured; to be obtained from salvage; not to be replaced since the next higher assembly is to be installed; or, due to failure, is in need of complete overhaul or retirement of the assembly or equipment from service.

Source codes are assigned to material at the time of provisioning. Known or anticipated usage is the primary factor in the assignment of source codes. The ability to manufacture an item within a naval activity is considered to be of secondary importance. In other words, items are normally source coded for purchase and stocking in the Navy supply system if usage is known or anticipated. Source codes for individual items may be revised as experience and usage develop.

Source codes are published as a column of the numerical index of the Illustrated Parts Breakdown, and in other publications as directed by the NavAirSysCom.

Source codes are provided in six series—P, M, A, N, X, and U.

Source code P series applies to items of supply system stock which are purchased in view of known or anticipated usage and which are relatively simple to manufacture within the Navy if necessary.

Source code M series applies to items which are not purchased but are capable of being manufactured at Navy fleet or overhaul activities. These items are normally manufactured upon demand and are not stock numbered.

Source code A series applies to assemblies which are not purchased.

Source code N series applies to items (nuts, bolts, screws, etc.) which do not meet established criteria for stocking and which are readily available from commercial sources. These items are purchased on demand.

Source code X series applies to items which, if damaged, would require uneconomical repair. The need for an item, or items, coded X will normally result in recommendation for retirement of that equipment from service.

Source code U applies to items which are not of supply or maintenance stocking significance.

Within each of the source code series, except U, there are one or more subcodes identified by a letter or number appended to the basic code number. These subcodes provide detailed information concerning the procurement or manufacture of various parts within the scope of the particular code series. The applicable Illustrated Parts Breakdown provides ready reference for each of the codes and subcodes as required.

The preceding sections have emphasized some of the many things that may be used to identify or aid in procurement or use of material. The senior AZ who is familiar witi the methods of identifying material is an asset to a maintenance organization, especially in performing maintenance supervisory duties.

AERONAUTICAL ALLOWANCE LISTS

This title is inclusive of publications identified as Allowance Lists (except advanced base lists), Initial Outfitting Lists, and Tables of Basic Allowances.

Naval Air Systems Command Allowance Lists, Initial Outfitting Lists, and Tables of Basic Allowances are prepared by the NavAirSysCom or the Aviation Supply Office. In nearly all instances ASO has the responsibility for preparation, but in all cases these lists are published by the direction of and approved by the NavAirSysCom. These lists contain the following:

1. The equipment and material (both consumable and nonconsumable) necessary to outfit and maintain units of the aeronautical organization in a condition of material readiness.

2. Substantially all items used with sufficient frequency to justify their issuance to all activities maintaining aircraft or equipment for which the lists are designed.

114346

3. Information concerning stock number, nomenclature, interchangeability, and supersedures.

4. A set of detailed instructions for the application and utilization of the publication.

5. A table of logistic data showing the total weight and cube of all material contained in the list.

In the final analysis, the equipment and spare parts listed in these publications are made available to aircraft operating and maintenance activities in accordance with assigned operational maintenance and logistics responsibilities through appropriate application of allowance lists and outfitting actions. The Aviation Supply Office has the responsibility for continually reviewing and updating the allowance lists.

INITIAL OUTFITTING LISTS

Initial Outfitting Lists are publications which indicate the range and quantities of maintenance spare parts considered necessary to support various aeronautical end items. These lists contain repair parts, such as airframe parts, electronic parts, engine parts, and general aeronautical equipment. The material covered by Initial Outfitting Lists is normally retained in supply department stocks until required for issue. This allowance of material is provided to ships or activities and is firm only at the time of initial outfitting. Increases and decreases in both range and/or quantities of material are based upon usage data of each activity concerned. Each series list is designed to support an aircraft, electronic equipment, or some other aeronautical article.

ALLOWANCE LISTS

These are publications which indicate the range and quantities of equipment and material considered necessary for maintenance support of assigned and/or supported aircraft. Generally, these items are inuse items required for daily or continual use, such as aircraft jacks, air compressors, and avionics test equipment.

TABLES OF BASIC ALLOWANCE

Publications listing equipment and material required by activities for performance of their assigned mission are known as Tables of Basic Allowance. They contain both shop equipment and common supporting spare parts. They cover allowances of tools and equipment required for use by such activities as Fleet Marine Force squadrons and target pilotless aircraft activities.

A complete listing of Aeronautical Allowance Lists, Initial Outfitting Lists, and Tables of Basic Allowance, with NavAirSysCom publication numbers and their effective dates, is contained in NavSup Publication 2002, Section VIII, Part C.

IDENTIFICATION AND TYPES OF ALLOWANCE LISTS

Allowance Lists and Initial Outfitting Lists are identified by the NavAirSysCom publication number 00-35Q (Series), while Tables of Basic Allowance are identified by the NavAirSysCom publication number 00-35T (Series). The following paragraphs discuss some of the various sections of allowance lists.

Section A, Standard Aeronautical Material and Naval Stock Account Material

Section a covers general material such as nuts, bolts, tubing, hose, paint, and other items common to the operation of all aircraft models. Both equipage and consumable supplies are shown in the Section A.

Section B, Aircraft Maintenance Parts

Section B contains airframe, engine, and accessories maintenance parts peculiar to each type of aircraft. A separate section B is issued for each model of aircraft.

Section C, Office Furniture and Laborsaving Devices

Section C lists the items and quantities of office furniture and laborsaving devices for the administrative support of deployable fleet air activities only.

Section G, General Support Equipment for All Types, Classes, and Models of Aircraft

Section G (Series) lists the quantities of handtools, handling and servicing equipment,

14347

Instructional Materials

- Dressmaker's dummies in various sizes
- Padding for dummies
- Copies of Information Sheet - Using the Dress Form (Appendix I)
- Men's and women's garments for demonstration and practice
- Various kinds of pattern pieces
- Guide sheets for evaluating fit of women's garments (Appendix H)
- Pictures or slides of correct and incorrect fit in men's clothing
- Sewing equipment and supplies

ACAI 1432

and material which are made available for maintenance support of aircraft as may be assigned or supported.

Section H, Flight
Operational Material

Section H is applicable to air task group commanders and all Navy and Marine squadrons operating aircraft or having aircraft assigned. It contains items and quantities of flight operational material considered necessary to maintain the concerned activities in a continual condition of operational readiness.

Section K, Naval Aeronautical
Publications and Forms

Section K outlines the general types and classes of aeronautical technical and training publications and forms which are provided as a commissioning allowance for various Navy and Marine Corps aviation activities. It lists those publications and forms which are issued by the Deputy Chief of Naval Operations (Air) and by the Naval Air Systems Command, but does not include publications provided to aviation activities by other Navy Department systems commands and bureaus, by fleet commands, or by non-Navy offices.

Section R, Aeronautical
Electronics Material

Section R comprises Allowance Lists and Initial Outfitting Lists of electronic equipment and material required for the test and maintenance of aeronautical electronic equipments within the Naval Establishment.

Section T, Special Maintenance
Support Equipment

Section T is applicable to Navy and Marine aeronautical maintenance activities and lists the allowances of special support equipment required for maintenance support of assigned aircraft. A separate section T allowance is published for each manufacturer.

Section Z, Special Equipment
and Spare Parts

Section Z includes mobile electric powerplant spare parts and equipment and spare parts support for aircraft support equipment.

The foregoing section list breakdown includes only those sections of professional interest to the AZ. The complete list includes allowance lists for arresting gear and catapults, photographic, aerological, etc.

ACCOUNTABILITY CODES

The accountability codes used in allowance lists and most Illustrated Parts Breakdowns are known as Material Accountability Recoverability Codes (MARC). MARC's are assigned only to aeronautical provisioned items to reflect the accountability, recoverability, and repair policy determined for an item of equipment of material required for the maintenance, repair, or rework of an end item. MARC is a system whereby a letter of the alphabet is used as a guidepost by personnel working with aviation material. This system helps personnel to determine the proper method of the following:

1. Requisitioning material with regard to inventory control and fiscal accounting procedures.
2. Accounting for material while in use.
3. Turn-in or disposition of material.
4. Repair or overhaul.

The following list defines the various material accountability codes:

B—Exchange Consumables

Code B is applied to items which are consumable or expendable but normally require item-for-item exchange for issue after the initial outfitting. Such items may contain precious metals, may be highly pilferable, or may be high cost items.

C—Consumables

Code C is applied to all other consumable or expendable items which do not require item-for-item exchange for replacement.

D—Equipage, Support Type

Code D is applied to end items of support equipment which are economical and practical to repair on a scheduled basis through a major rework activity. Code D items are maintained on a custodial signature basis and must be surveyed when lost or missing or when beyond

14348 TAC41

economical repair. After initial outfitting, Code D items require item-for-item exchange for replacement. Every effort should be made to repair Code D items locally or through fleet support activities prior to turning in the item to the supply system as non-RFI material.

E—Equipage, Locally Repairable, Support Type

Code E is applied to end items of support equipment which are to be repaired locally by the using or fleet support activity within their assigned maintenance responsibility. Code E items are maintained on a custodial signature basis when in use, require item-for-item exchange for replacement, and require surveying when lost or missing. The cognizant NavAirSysComRep may authorize repair of E items through customer service from a major rework activity in order to meet operational commitments.

R—Equipage

Code R is applied to repairable (except end items of support equipment) items which are economical and practical to repair on a programed basis through a major rework activity. Code R items are repaired by local activities when the extent of the required repair falls within the maintenance capability of the activity. After initial outfitting, these items are issued only on an exchange basis or when necessary to replace an item expended by approved survey.

L—Equipage, Locally Repairable

Code L is applied to repairable (except end items of support equipment) items which can be repaired by deployable squadrons within their assigned maintenance responsibility upon consideration of the following factors:

1. Manhours and skills required to perform the repair.
2. Total cost of providing necessary support equipment to perform the repair.
3. Total cost of providing necessary repair parts to perform the repair.

Items coded L are scrapped when economical repair is beyond local activity capabilities. After initial outfitting, issues of Code L items are made only when exchange procedures provide for turn-in of the replaced item or when necessary to replace an item expended by approved survey.

DEVIATIONS FROM ALLOWANCE LIST REQUIREMENTS

It is the policy of the NavAirSysCom to make available to each Navy activity the authorized equipment and repair parts necessary to insure operational readiness. Allowance list requirements are not mandatory and deviations are approved as pointed out in the following paragraphs.

Type, Force, and major operating commanders, or their subordinate logistics commanders, may authorize deviations from allowance list requirements including one-time in-excess issue of equipment for a requirement not considered generally applicable to other activities of the same type, or for independent operations of detached activities.

Organizational and Intermediate maintenance activities often have requirements for equipment which does not appear on existing allowance lists. In some cases the equipment is requested because it is considered superior to existing equipment or it may be the result of an entirely new requirement; that is, for rework of a component or to perform repairs or services for which no previous capability existed.

In order to assure that each request for deviation is properly reviewed and evaluated for validity and possible application to other maintenance activities, the originating activity should submit an official request to the Naval Air Systems Command Headquarters, via the chain of command (including the cognizant NavAirSysComRep). The following general procedures are followed in approval or rejection for a new piece of support equipment where no previous capability or need existed.

The request, together with complete justification, should be forwarded via the chain of command to the NavAirSysComHq. The request should not be made through supply system channels. The type commander normally identifies, on the forwarding endorsement, the Intermediate maintenance activity which will perform the equipment evaluation if different from the requesting activity.

The NavAirSysComRep normally investigates the request and indicates on the forwarding endorsement the availability of the requested equipment from existing resources. Upon review and approval, the NavAirSysComHq provides the activity concerned with the equipment is considered a prototype and is for

14349 U&EA1

evaluation. No additional equipment is normally procured until the validity of the need can be determined. During the evaluation, the type commander and cognizant NavAirSysComRep performs monitoring actions and provides additional assistance as required.

The completed documentation of the evaluation is forwarded via the chain of command to the NavAirSysComHq. In the forwarding endorsement, the type commander normally suggests a criteria for allocation of equipment to other activities. Upon review of the evaluation report, the NavAirSysComHq notifies all concerned of the action taken. In case of approval, this includes ASO so appropriate action may be taken to insure updating allowance lists.

AIRCRAFT MAINTENANCE MATERIAL READINESS LIST (AMMRL) PROGRAM

This program has provided for the development of data and documentation needed to determine and establish firm support equipment requirements and inventory control of aircraft maintenance support equipment. It provides for the construction of an Individual Material Readiness List (IMRL) for each aircraft maintenance activity, by name, prescribing items and quantities of aircraft maintenance material required for material readiness of that specific activity to which the list applies. This program also provides for the construction of material readiness lists to indicate the total quantities of each item authorized within stations, logistic areas, and major operating command areas.

Within the AMMRL program there are several material readiness lists; however, only two are discussed here.

The Application Data Material Readiness List (ADMRL) is used to specify the requirements for each item of aircraft maintenance support equipment against each level of maintenance and selected ranges of each aircraft, engine, propeller, and system for which each item is needed. This data is developed primarily from Aeronautical Allowance Lists. Through the use of electronic data processing machines this data is used to develop Individual Material Readiness Lists.

The IMRL specifies items and quantities of aircraft maintenance support equipment required for material readiness of the aircraft maintenance activity to which the list applies. As previously stated, this list applies to an activity by name. The NavAirSysComRep is responsible for the preparation of the IMRL for each activity in his cognizant area. It is prepared by extracting from the AMMRL those applicable portions which pertain to the specific aircraft and maintenance material assignments of the activity for which the list is developed.

The IMRL should be continually reviewed and up-dated by each activity to support current and anticipated changes in aircraft maintenance support equipment requirements. Because the IMRL is continually reviewed and updated and approved by the cognizant command, it is the firm mandatory material readiness list of the activity to which the list applies. The IMRL is actually a composite listing of the various allowance lists previously discussed.

MATERIAL ISSUE AND TURN-IN

As mentioned earlier in this chapter, the senior AZ performing supervisory duties in a maintenance activity has certain responsibilities for supporting the production personnel. These duties might include providing assistance in the areas of material requisitioning and turning in inoperative material. Material support has an important bearing on aircraft readiness; therefore, senior AZ's should be familiar with the local supply activity, material requisitioning, and material turn-in.

Probably one of the most abused areas in naval aviation is in the area of material procurement. This is true because most times when a part or some material is needed the user wants it immediately and does not care what procedures are used in its procurement; just so he gets the desired material. Standard requisitioning procedures and priorities have been established and these should be followed by all concerned if the supply system is to function properly.

SUPPLY ACTIVITY

The mission of the supply activity is to support the operational and maintenance efforts of the activity/ship. Stocks of aviation oriented material carried are tailored and replenished to this end. Positioning, replenishment, and control of stocks of material in maintenance areas are carried out as a result of joint decisions by the Supply and Maintenance Officers concerned. They determine the range, depth, and related procedures. The Navy

14350

Maintenance and Material Management System requires that the cost of material used in maintenance be determined and accumulated in such manner and detail that weapons system costing can be measured. Usage is finely defined as to stock number, within component, within system, within equipment/weapon/aircraft, in a particular squadron, located in a specific operational area, at a definite point in time. These data are used as an inventory management tool to determine geographic and strategic distribution of stocks of material. In addition, the data will be invaluable in establishing the material portions of work standards in maintenance.

Supply Support Center

Maintenance organizations have one point of contact with the supporting supply activity. This single supply contact point is the Supply Support Center (SSC), which responds to all material requirements of the maintenance organizations. The SSC is an internal organization of the local supply activity. It is made up of three sections—the Supply Response Section, the Component Control Section, and the Supply Screening Section.

Supply support is available consistent with the operating hours of the maintenance activities supported. If maintenance is being performed 24 hours a day, then supply support is available 24 hours a day.

The supply support center maintains rotatable pool material which consists of repairable ready-for-issue items reserved primarily to satisfy the requirements of Organizational level maintenance. Items maintained in the pool are capable of being repaired by the local Intermediate maintenance activity, have application relationship to weapon systems supported by local Intermediate maintenance activities, and have an average Organizational maintenance level removal rate of at least one per month. Defective components are turned in to Intermediate level maintenance for repair. The defective components repaired to an RFI condition are then returned to the rotatable pool to replace the components previously issued.

Generally, items included in a rotatable pool are repairable items of supply which are under the issue control of the local supply officer. However, instances may occur when it is desirable to position some items or assemblies (such as a pre-soaked carburetor, built-up wheel assembly, built-up prop, etc.) in the pool for use by Organizational and Intermediate maintenance activities. Pre-positioning of items of this nature is acceptable as long as they aid in decreasing NOR time.

The local supply officer and aircraft maintenance officers concerned determine the range and quantity of each item required in the rotatable pool. Two elements used in this determination are the local repair cycle time and the local removal rate. The local repair cycle time is the average total elapsed time between removal of a component and the complete local repair of the item into an RFI condition. The local removal rate is the average number of defective components removed over a 3-month period, for which replacement RFI components were required.

After the components and the quantity of each that will be included in the pool have been determined, the supply officer publishes an official list of pool items. This listing provides a ready reference for the components carried in the pool. RFI rotatable pool items are withdrawn from the pool by the local supply officer only under the following conditions:

1. When actual usage indicates the item/quantity can no longer be justified as a reservation, and the aircraft maintenance officer concurs.
2. When requested by the aircraft maintenance officer.
3. Only as a last resort to satisfy non-local system requirements.

In order for the rotatable pool to fully serve its intended purpose there must be complete cooperation between the maintenance and supply organizations. Organizational maintenance activities must expedite return of defective components to supply so that these components can be delivered to the Intermediate activity for repair. The Intermediate activity must complete repairs in an expeditious manner so that the repaired components can be returned to supply to be placed in the rotatable pool. Then, the supply organization is able to offer maximum support in the form of RFI components to insure maximum aircraft readiness.

Low value, fast moving consumable items are preexpended from supply. Such materials are located in the maintenance area; and the establishment, maintenance, and replenishment of pre-expended bins are the responsibility of the supply organization.

14351
S2641

SUPPLY RESPONSE SECTION.—The Supply Response Section (SRS) is responsible for preparing all necessary requisitions (DD Form 1348) and related documents required to obtain material for local maintenance use in direct support of weapon system maintenance. The maintenance organization verbally notifies the supply organization of the need of such material. When material is available locally, the time frame for processing and delivery is as follows:

Priority	Process/Delivery Time
1-3	1 hour
4-8	2 hours
9-20	24 hours

The SRS is responsible for receipt, storage, and issuance of all ready-for-issue pool components. It is responsible for physical delivery of RFI material to maintenance organizations, and the pickup of defective components from the Organizational maintenance activity and subsequent delivery to the Intermediate maintenance activity. Actual maintenance personnel are not involved in the physical movement of material between organizations.

This section also performs technical research in regard to completion of requisition documents as well as determining the status of outstanding requisitions and relaying this status to the customer upon request.

COMPONENT CONTROL SECTION.—The Component Control Section (CCS) maintains status records of all components being processed in the Intermediate maintenance activity. This section is also responsible for maintaining status records for all rotatable pool items.

SUPPLY SCREENING SECTION.—The Supply Screening Section (SSS) is responsible for initiating disposition action on components that cannot be repaired by the local Intermediate maintenance activity. Using listings and directives from inventory managers, screening personnel determine disposition of components in question, including prospective consignee and packaging and preservation requirements prior to movement of material.

MATERIAL CONTROL WORK CENTER

The material control work center in a maintenance activity performs a staff function, and as such provides support and services to the production divisions. It exists for the primary purpose of insuring that maintenance requirements for parts and materials are made known to the supply organization in a timely manner in order to prevent work stoppages and grounding aircraft. Material control insures that parts and materials made available to maintenance are systematically utilized and not allowed to accumulate or to become depleted. It serves as the single point of contact within the maintenance organization for the conduct of business with the supply organization.

The material control work center provides material support to their cognizant organization by accomplishing the following general functions:

1. Pass all requirements for material required for direct support of weapon system maintenance to the SSC. A material control register is maintained for these items.
2. Prepare documents for materials required for indirect support of weapon system maintenance. Examples of materials for which documents are to be prepared are aviation fuels and lube oils, rags, and flight jackets. A separate requisition record log is maintained for these items.
3. Maintain liaison with the supporting SSC on maintenance material matters to insure that material needs of the organization are satisfied.
4. Establish delivery points for all material and insure that material received is expeditiously routed to the applicable work center.
5. Furnish technical advice and information to the supply activity on the identity and quantity of supplies, spare parts, and materials required for maintenance actions.
6. Establish procedures to insure the periodic inventory of tools and the adequate accountability of material and equipment on custody to the cognizant organization.
7. Initiate surveys in the event of loss, damage, or destruction of accountable material.
8. Keep the maintenance control work center advised of the overall supply situation as it affects the activity.
9. Perform cost and allotment record accounting, charting, and budgeting of cost applicable to the cognizant organization.
10. Monitor the operation of toolrooms and maintain an updated IMRL.
11. Maintain inventory control of authorized allowances of material.

The material control work center is responsible for the coordination of material ordering, receipt, and delivery. This is done in such a manner as to insure that the correct material

14352

is ordered and that it reaches the work center within the specified time frame.

The foregoing functions of the material control work center apply to both Organizational and Intermediate level activities. Some of the functions which are applicable to one level only are listed in the following paragraphs.

Intermediate Level

An Administrative Screening Unit has been established in the material control work center of Intermediate maintenance activities. This screening unit does the following:

1. Positively identifies material and determines if it is within the repair capability of the Intermediate Maintenance Activity (IMA).
2. Insures that all required documentation is affixed to the component (that is, logs, records, MAF, etc.).
3. Notifies maintenance control of the receipt of defective components for scheduling into the IMA.
4. Transfers the defective components to the appropriate work center when directed by maintenance control.

All components received in the IMA material control receive screening to determine if the item is within the check, test, or repair capability of the IMA. As a result of this screening, components requiring maintenance within the IMA capability are reported to maintenance control as ready for induction. Items beyond IMA capabilities are returned to the Supply Support Center with appropriate recommendations for disposition. When work on components in the IMA has been completed, the components, together with required records, are returned to material control for appropriate routing back into supply organization.

Organizational Level

In addition to the general functions, the material control work center in Organizational level activities is responsible for the following:

1. Verification of NORS (Not Operationally Ready Supply) requisitions and maintenance of current NORS status records.
2. Inventory of aircraft upon receipt and transfer and maintenance of inventory records.

When removed components are generated as a result of the maintenance effort, material control insures that the SSC is notified to make a pickup. These components must be accompanied by record cards and logs, when applicable, plus the number two, three, and four copy of the Maintenance Action Form.

Material Control Register

The Material Control Register is used by Intermediate and Organizational level material control work center to record all material requested from the Supply Support Center in direct support of weapon system maintenance. Space is provided to record essential information considered necessary to monitor operating target (OPTAR) funds. This information includes part number, priority, quantity, price, date and time ordered, and date and time received. Maintenance control uses the time ordered and time received to help determine Not Operationally Ready Supply (NORS) time used in fulfilling readiness reporting requirements.

Material Requisitioning

The Military Standard Requisitioning and Issue Procedure (MILSTRIP) and Uniform Material Issue Priority System were developed by the Department of Defense to provide a common supply language and more effective supply system operations within the military establishment. This system standardizes forms, formats, codes, procedures, and the priority system.

MILSTRIP employs two forms for the requisitioning and issuing of material. The Single Line Item Requisition Document (Form DD 1348) is the basic request document submitted to the applicable supply echelon for material requirements. The issue document is the Single Line Item Release/Receipt Document (Form DD 1348-1). Form DD1348-1 is also used to return RFI material to the supply system. As previously stated, these forms will be prepared by the Supply Response Section of supply for all material requested in direct support of weapon system maintenance and by the material control work center for material requested in indirect support of weapon system maintenance.

Under the MILSTRIP priority system there is no decision to be made in assigning priorities. The urgency of need combined with the unit's military importance when applied to the priority number chart (table 7-2) indicate the proper priority number and no deviation is allowed.

The force/activity designators represent categories of activities in descending order of military importance, ranging from the combat forces under I to the miscellaneous activities under V. Every activity is assigned one of the five force/activity designations according to

14353

Table 7-2.—Priority number chart.

Force/activity designator	Urgency-of-need categories			
	A	B	C	D
I	1	4	11	16
II	2	5	12	17
III	3	6	13	18
IV	7	9	14	19
V	8	10	15	20

their military importance. These designations are as follows:

I—COMBAT—The highest order of military importance. This designator is not used in peacetime unless approved by the President or the Joint Chiefs of Staff.

II—POSITIONED—U.S. Forces positioned and maintained in a state of readiness for immediate combat or direct combat support.

III—READY—U.S. Forces maintained in a state of readiness to deploy for combat.

IV—RESERVE AND SUPPORT—U.S. active and selected reserve forces planned for employment in support of approved joint war plans. This category includes training units and units in training for scheduled deployment.

V—OTHERS—All units not otherwise assigned.

Force/activity designators are assigned by the Secretary of the Navy, the Chief of Naval Operations, and Commanders in Chief of Fleets. Authority to make assignments may be delegated to Fleet Commanders with the exception of I—COMBAT. Each activity is advised by the appropriate military commander of the assigned designator which governs the procurement of material for that activity.

The letters across the top of table 7-2 represent different degrees of urgency, in descending order of need, from an extremely serious need under A to routine stock replenishment under D. The urgency category is selected by the requesting activity. Definitions of the urgency-of-need categories for aviation units are as follows:

A—Material and equipment for immediate installation or use to effect emergency repairs or replacement for an aircraft mechanically incapable of flight, or an aircraft incapable of performing its primary mission.

B—Material required to effect emergency replacement or repairs without which the operational capability of the activity will be impaired and decreased effectiveness and efficiency in accomplishing assigned operational missions and tasks will result.

Material required to effect emergency replacement or repairs without which the activity can operate only temporarily as an effective unit in performing its assigned operational mission and tasks. This includes material required for aircraft overhaul work stoppage.

C—Material required for emergency repairs of replacement of specific units of inoperative equipment or systems not essential to the operational effectiveness or safety of the force/activity.

Material required for scheduled deployment.

D—Material required in preparation for operational readiness.

Material required for scheduled maintenance of a specific aircraft or system.

Material required for initial outfitting and filling of allowances.

All stock replenishment actions other than previously prescribed.

If a squadron or unit has been assigned force/activity designator III and a work center supervisor determines that a part or some material is needed which if not received will impair the capability of the aircraft to perform its assigned mission, then the priority assigned must be number 6. The only other priorities available to force/activity designated III units or squadrons are 3, 13, and 18.

There are two allowable exceptions to the force/activity designator governed priority number system. Medical or disaster supplies and essential clothing may be requisitioned under priorities 3 and 6, respectively, by any activity regardless of its force/activity designator.

Material Turn-In

There are two main reasons for turning in material—the first and most common is the turning in of a damaged, wornout, or otherwise inoperative part in exchange for a like RFI item; and second, returning of material for credit, such as excess material or material received in error.

When it is determined that a needed part is an exchange item, the old part should be cleaned of grease and dirt, drained, flushed, or purged as necessary before turning it in. It is the responsibility of the maintenance

personnel to attach aircraft equipment condition tags directly to the repairable item. An aircraft equipment condition label is applied to the exterior of the container. All turn-in material should be returned, if practicable, in the container in which the new item was received.

Activities placing items into shipping containers are responsible for the accuracy and completeness of information on the tag and the label, including the necessary obliteration of previous markings on the container which no longer apply. The primary reason for these tags and labels is to provide a means of identification and condition without disruption of packaging or preservation. These tags and labels indicate the required disposition to those processing the material through channels.

When a defective repairable item is turned in, the following forms are required: copies two, three, and four of the multicopy Maintenance Action Form and the Accessory and Component Service Record, when applicable. The supply department uses copy two of the MAF for bookkeeping purposes. Copies three and four of the MAF accompany the item to the Intermediate maintenance activity. When repair is completed by the IMA, copy four of the MAF is attached to the RFI item and the item is returned to the supply system.

If material being turned in is no longer required and is RFI, a Single Line Item Release/Receipt Document (DD 1348-1) is submitted with the item. RFI means ready for issue in all respects—preservation still intact and item in original or reusable container with seals unbroken.

Parts Kits

Supporting items and material for the maintenance, repair, and rework of selected repairable type items are procured, stocked, requisitioned, accounted for, and used on a kit basis as a single item. These parts kits should not be confused with Change Kits which are issued to perform a one-time modification of an item, nor with Interim Fleet Maintenance Support Kits which consist of a minimum range and quantity of parts and material to support the items until regular parts kits become available as a result of normal provisioning action.

A repair kit consists of a group of maintenance or overhaul parts that are bought, packaged, and stocklisted as a single item regardless of the supply classification of the items contained in the kit. Normally, these parts have either a very low unit cost or have a high replacement rate in overhaul or repair of the next higher assembly. Depending upon the complexity of the item to be repaired, there can be one or more kits needed for its repair. Repair parts kits are designed to serve three separate requirements as described in the following paragraphs.

C KIT (CURE-DATED OR SOFT GOODS).—This kit provides cure-dated items such as diaphragms, packings, and O-rings. The C kit may also contain soft goods not subjected to age controls such as gaskets and seals, plus metallic items such as screws, nuts, and washers required to be removed when cure-dated or soft goods type material are replaced. When mixed categories of cure-dated parts are packaged in a single container, the controlling cure-date of the package is that of the oldest cure-dated part in the package. If cure-dated kits become overaged due to the expiration of the storage limitations, the kit is administratively disposed of as excess material.

D KIT (OVERHAUL).—This kit contains hard good repair parts required at the time of overhaul. This kit does not contain cure-dated parts nor any metallic item which is placed in the C kits, thus both are required at the time overhaul maintenance is being performed.

F KIT (FLEET).—This kit provides those items that are required to be replaced at Intermediate and Organizational maintenance levels. Replacement of F kit items normally does not require special tools or equipment. This type kit does not contain cure-dated parts.

Part numbers for repair kits are listed in the applicable Illustrated Parts Breakdown and, in some cases, the Maintenance Instructions Manual.

SURVEYS

Rules and regulations concerning surveys and the responsibility connected with the accounting for government property are of primary importance to every man in the naval service. Personnel of the AK rating are considered the technical experts in matters pertaining to surveys; however, the senior AZ may be required to initiate or assist in the preparation of a request for survey.

14355

A survey is the procedure required by Navy Regulations when property must be reevaluated or expended from the records due to loss, damage, deterioration, or normal wear. The survey request provides a record showing the cause, condition, responsibility, recommendation for disposition, and authority to expend material from the records. The Survey Request, Report, and Expenditure (NavSup Form 154) is used to survey property, except when a survey is due to discrepancies incident to shipment of material. The Report of Survey (DD Form 46) is used in cases where property is surveyed due to discrepancies incident to shipment of material.

TYPES OF SURVEYS

A FORMAL survey is required for those classes of material or articles so designated by the systems command or office concerned, or when specifically directed by the commanding officer. A formal survey is made by either a commissioned officer or a board of three officers, one of whom, and as many as practicable, must be commissioned officers. The formal survey board is appointed by the commanding officer.

Neither the commanding officer, the officer on whose records the material being surveyed is carried, nor the officer charged with the custody of the material being surveyed, may serve on a survey board.

INFORMAL surveys are made by the head of the department having custody of the material to be surveyed. Informal surveys are used in all cases when a formal survey is not required or directed by the commanding officer. A formal survey can be directed by the commanding officer when circumstances are considered to warrant such action.

PREPARATION OF REQUEST FOR SURVEY

A request for survey may be initiated by a department, division, or section head or a designated subordinate as prescribed by local regulations. Normally, requests for survey are initiated in the department having custody of the material being surveyed. The initial survey request is made on a rough copy of NavSup Form 154. A statement by the originator is placed on or attached to the request for survey relative to the condition of material, including the following:

1. Cause or condition surrounding the loss, damage, deterioration, or obsolescence of material.
2. Responsibility for cause or condition of material or reason why responsibility cannot be determined.
3. Recommended disposition of material or action to be taken.

Upon receipt of the rough copy, the designated group or section prepares a sufficient number of smooth copies of the request for distribution in accordance with local regulations. It is then forwarded to the commanding officer who will determine whether the survey request is to be formal or informal. If formal, the survey request is forwarded to the designated surveying officer(s); if informal, it is forwarded to the head of department for survey action. The surveying officer(s) or department head, as appropriate, conducts the survey.

The statement by the originator as to cause, condition, etc., is attached to the smooth request for survey for evaluation by the surveying officer(s). After the survey has been completed by the head of department or surveying officer(s), it is returned to the commanding officer for review and action. After approval by the commanding officer, the survey is forwarded to the cognizant fleet command and/or systems command for final review and approval when so required. In the absence of specific instructions, surveys are not forwarded to the Naval Air Systems Command for final review and approval.

After approval, the supply officer expends and replaces items as directed by the approved survey. Requests for replacement of surveyed items must be accompanied by a certified copy of the approved survey request.

DISTRIBUTION OF SURVEYS

Copies of a survey are distributed as follows:

1. One copy to the originator of the survey request.
2. One copy to the surveying officer, board, or head of department.
3. The original and three copies to the officer carrying the surveyed material on his records, except when the original is forwarded to a systems command or office for approval. (See item 4.)
4. The original to the cognizant systems command or office when required for final

review and approval. The original is returned to the officer carrying the surveyed material on his records unless the systems command or the supply demand control point requires an information copy approved by the commanding officer. In such cases, a copy is returned to the officer carrying the surveyed material on his records.

5. Any additional copies as may be required by local regulations.

6. One copy (in addition to the regular distribution) to the shipping officer when material shipped on U.S. Government Bill of Lading (Standard Form 1103) is short or material is damaged. A copy is not sent to the shipping officer for material that was shipped under a commercial bill of lading since sufficient information is furnished on the delivering carrier's shipping papers or the Notice of Rejection (NavSup Form 160).

In all cases a certified copy of the approved survey must accompany requests submitted for replacement of surveyed material.

EMERGENCY DISPOSAL

The commanding officer may direct immediate disposition of surveyed material prior to the receipt of systems command or other approval if this action is considered necessary to safeguard the health or safety of his command.

CULPABLE RESPONSIBILITY

When a person in the naval service is found to be culpably responsible (deserving blame) by a surveying officer or board, the reviewing officer refers the entire matter to such a person for a statement. The reviewing officer must then take such disciplinary action as the circumstances require. He notes on the survey form the action taken and informs the Chief of Naval Personnel and the Bureau or systems command concerned as to the disciplinary action taken. In the case of officers, he must make recommendations as to the inclusion of a statement of the action taken in the record of the person concerned and inform such person of the final decision in the matter. Action on the survey in respect to the material involved is not withheld pending disciplinary action.

14357

TOPIC 4 - REPAIR TECHNIQUES

Competencies

- Alter, repair, and replace a zipper.
- Repair ripped seams by hand and machine.
- Replace and repair outside pockets.
- Replace inside pockets in a jacket or coat.
- Replace lining in a coat or jacket.
- Mend holes or tears.

Motivating Procedure

Have trainees describe personal and family clothing repairs that they have made recently. Discuss if the methods used would be satisfactory for a paying customer.

Learning Experiences

- Show trainees a variety of repair problems that were identified in the class survey. Use examples of repair techniques, wall charts, or duplicated materials to help trainees identify possible solutions to repair problems. Assign several repair jobs to each trainee and display and discuss completed work.
- Demonstrate how to make various kinds of patches and darns such as fringed patch, hemmed patch, chain stitch darn for knits, and french weaving. Have students practice and develop standards for finished products.
- Set up a repair clinic using garments from trainees' family wardrobe. Have trainees estimate cost of repair in terms of time, money, and wearability.

Instructional Materials

- Garments in need of repair
- Wall charts and duplicated material for student reference
- Examples of proper repair techniques
- Sewing equipment and supplies.

ABSTRACT - This booklet is one in a series of booklets of supplemental lessons in food and nutrition prepared by the Extension Service of the U.S. Department of Agriculture and is designed for use by trainer agents in on-the-job training of Extension aides to provide them with information about food needs of family members and with teaching methods to use in helping families. Lessons are: (1) Cultural Food Patterns, (2) Combating Food Misinformation, (3) Sizes of Servings, (4) Digestion and Absorption of Food, (5) Special Diets and How to Handle Them, (6) Weight Control, and (7) Food Needs of Infants, the Preschool Child, School Children, Teenagers, Pregnant and Lactating Women, and the Elderly. Purposes, presentation suggestions, learning activities, references, and audiovisual materials accompany each lesson. An introductory section provides additional suggestions for the trainer agent and lists recommended references. Related booklets are available as VT 012 841-VT 012 843, all in this issue. (SB)

Food Needs of Family Members is one of a series of booklets of supplemental lessons in food and nutrition designed for use in on-the-job training of Extension aides. Purpose of these lessons is to give the aides more information about food needs of family members and to provide them with practical teaching methods that they can use in helping families.

FOOD AND NUTRITION

Supplemental Lessons for Training Extension Aides

FOOD NEEDS OF FAMILY MEMBERS

Purpose

These lessons were written to help trainer agents prepare aides for work with families in the Food and Nutrition Education Program. They help the aides understand the more specific needs of family members of different ages and with varying dietary problems.

This series follows the 15 basic lessons in nutrition given in the initial training for aides and leaders and it enlarges lesson 6 - Food Needs Throughout Life - and Lesson 7 - Feeding Young Children. The information can be adapted by the aides for the families they work with. They can also be used in teaching groups of adults and youth.

The first lesson gives the aides information and makes them more aware of background such as cultural food patterns of the families. The next five tell how to combat food misinformation, what is meant by a serving, more about digestion and absorption of foods, and how to handle the problems of special diets and weight control. Lessons 7 through 12 take up the needs of the infant, preschool child, the school child, teenagers, pregnant and lactating women, and the elderly.

TRAINER AGENT'S RESPONSIBILITY

References are suggested for the agent's use with each lesson. The agent will find it helpful to assemble these references before starting the lessons and to use them in her preparation for teaching.

References are also suggested for the aide's use. The agent should be selective in the references she gives to aides. Order those selected well in advance.

Go over references thoroughly with the aides so that they know what is in each reference.

Professional people in related fields may be asked to participate in training meetings. Such participation should be planned well in advance.

14365

A working relationship with each aide should already be established as a result of the initial training period. Effective communication remains vital in teaching. Before teaching supplemental lessons, the trainer agent may wish to review purposes of the training and importance of aides' participation.

This suggested checklist will help to assure that all necessary preparations for the in-service training sessions have been made:

___Meeting place with necessary facilities has been obtained.

___All references needed to complete the lessons have been assembled.

___Local public health service and library have been checked for additional references.

___All visual materials and equipment needed to teach the lessons are on hand.

___All reference materials needed for the aides have been obtained.

___All lesson plans have been carefully studied so that the overall content of the course is fully understood.

___Sufficient time has been allowed to complete each lesson.

ADAPTING THE LESSONS TO YOUR AIDES

Guides used in teaching the basic lessons also should be followed in teaching the supplemental lessons.

Adapt training classes to meet the needs of your group. Here are some ideas to keep in mind:

1. Simplify. Do not try to cover too much material in one lesson. Pick out the most important points and emphasize them.

2. Use colorful visuals and a dynamic presentation to help make each lesson appealing.

14365

14366

3. Emphasize good nutrition elements in the food the aides are now eating. Point out how small changes can often result in a more balanced diet.

4. Stress foods rather than nutrients.

5. Involve the aides in training meetings in as many ways as possible.

EXTENDING INFORMATION

The information given in the supplemental lessons may be effectively used in other ways, such as adaptation for use in training volunteer leaders or in newsletters or newspaper articles. A series of radio or television programs based on the lessons will extend to a larger audience the ideas that aides are promoting.

FOOD NEEDS OF FAMILY MEMBERS

Lesson 1: CULTURAL FOOD PATTERNS

PURPOSE

Trainer agent to help aides:

1. Understand factors that influence food patterns.

2. Recognize cultural subgroups in community and their food patterns.

PRESENTATION

- Have a food tasting party. Prepare some foods that are unfamiliar to the group as well as foods they know. Also, serve foods in an unfamiliar way (for example, pears or other locally grown fruits or vegetables cut into cubes). Observe reactions of the group to the foods.

- Discuss reactions to the food tasting. Point out positive and negative attitudes, influence of peer acceptance, and general reactions.

- Discuss some factors that influence foods a person eats. Refer to the listed references for background information. Ask the aides to give examples of how the following influence eating habits:

  - childhood habits
  - family members
  - peers
  - religion
  - status
  - security
  - culture or ethnic group

- Show the National Dairy Council poster "What Did You Have for Breakfast this Morning?" Ask the aides the following questions to stimulate discussion:

ATCAL

14373

207

- Do all of these children eat the same foods for breakfast? Why or why not?

- Does what we eat really matter?

Discuss the eating habits and related background information of ethnic groups in the community:

- nationality background
- location of ethnic groups in community
- family characteristics (extended family, size, etc.)
- religion
- occupations
- facilities for eating and cooking
- frequency of meals
- facilities for buying and obtaining food
- kinds and proportion of foods in diet
- methods of preparing and serving foods

. Using foods or pictures, have the aides show how the foods eaten by a particular ethnic group fit into the Daily Food Guide. Have the aides suggest additional foods so that some from all food groups are represented in the diet. (Aides may wish to use their own version of the Daily Food Guide made in Lesson 2 of Food and Nutrition...Basic Lessons.)

. Discuss this statement: Food habits, good or bad, are hard to change.

. Have aides understand food patterns of homemakers by studying several dietary recalls. Discuss food groups most lacking.

APPLICATION OF LESSON BY AIDES

Aides understand some of the factors which influence food patterns.

Aides recognize food patterns of ethnic groups among specific families in community, what food groups are represented, and what food groups need emphasis in the food patterns.

14375

FOOD NEEDS OF FAMILY MEMBERS

Lesson 2: COMBATING FOOD MISINFORMATION

PURPOSE

Trainer agent to help aides:

1. Identify some common food facts and fallacies.

2. Learn the dangers of food misinformation.

3. Recognize indications of food fads and fallacies.

4. Learn sources of reliable nutrition information.

PRESENTATION

- Give the true-false quiz on food facts and fallacies. Note the amount of misinformation among aides and discuss questions on quiz.

- Have aides tell and discuss other food fads or fallacies.

- Discuss the dangers of food fads and fallacies:

  - Essential nutrients are often lacking in a fad diet.

  - Medical attention to a serious ailment is often delayed while a food quack attempts to treat the condition. Emphasize that the physician is the only person qualified to diagnose and treat illness.

- Emphasize that, according to the American Medical Association, about 10 million Americans squander $500 million each year on food fads. The victims are found in all educational and economic levels. Chronically ill or aged persons are especially vulnerable. It is difficult to identify quacks because they often represent themselves as doctors and nutritionists. They lecture, write, and promote misinformation through advertising. Products include "miraculous" food as supplements, pills, gadgets, cooking equipment, service devices, treatments, or books.

14376

UNIT 4 - ELEMENTS AND PRINCIPLES OF DESIGN

Competencies

- Recognize those features of design which may be altered.
- Make alterations in garments that utilize the elements and principles of design.

Motivating Procedure

Exhibit two dummies, each dressed in an unbecoming style. Pad one dummy to simulate a short, stout figure and pad the other dummy to simulate a tall, slender figure. Have students identify the reasons for the poor visual efforts.

Learning Experiences

- Demonstrate fundamental principles of art and elements of design by using pictures, garments, fabrics, and silhouette kits. See Appendix L.
- Divide class into groups of two or three trainees. Have each group plan several garments of good design with the aid of a silhouette kit and then present their ideas to class using an opaque projector.
- Have trainees explain the elements and principles of design they need to consider when making various types of alterations.

Instructional Materials

- Dummies padded to simulate extreme figure types
- Pictures or actual garments and fabrics showing elements and principles of good design
- Silhouette kits (Appendix L)
- Clothing needing alterations
- Dresses for dummies

ACAI 1435

- List indications of quackery:

  - guarantees of quick cures

  - claims of "special" or "secret" formulas that can cure one or more diseases

  - case histories or testimonials to promote products

  - products used to replace surgery, X-rays, or medically approved drugs

  - statements of disasters which may happen if products are not used

- List sources of reliable nutrition information:

  - individuals such as Extension home economists, home economics teachers, home economists employed by other agencies, physicians, dietitians with hospitals, medical clinics, school lunch programs, Extension nutritionists, and public health nutritionists

  - organizations and agencies such as the U.S. and State Departments of Agriculture, Food and Drug Administration, Public Health Service, State and American Medical Associations, State and American Dietetic Associations, State and American Public Health Associations, State and American Home Economics Associations, and Better Business Bureaus.

APPLICATION OF LESSON BY AIDES

Aides learn to recognize food misinformation.

Aides help homemakers understand differences between food facts and fallacies.

Aides encourage families to seek reliable nutrition information.

FOOD FADS QUIZ

Directions: Indicate whether the statement concerning foods and nutrition is true or false, circling T for true and F for false.

	True or False
1. Adults do not need milk.	T F
2. A good way to reduce is to omit breakfast.	T F
3. Milk should be included in a weight-reducing diet.	T F
4. Fish and celery are "brain" foods.	T F
5. Toast has fewer calories than untoasted bread.	T F
6. Margarine has fewer calories than butter.	T F
7. Omit meat, eggs and milk from the diet to cure arthritis.	T F
8. Citrus fruits are "acid forming" in the body.	T F
9. Milk causes constipation in adults.	T F
10. Grapefruit aids reducing.	T F
11. Dark bread has fewer calories than white bread.	T F
12. Fruit and vegetable juices contain calories.	T F

14379

13.	Vegetables and cereals produced in poor soil are of very low food value.	T F
14.	Food stored in an open can in the refrigerator is dangerous.	T F
15.	Wheat germ, yeast, and blackstrap molasses can prevent nervousness, correct baldness, and help digestion.	T F

14380

ANSWERS TO FOOD FADS QUIZ

1. False. Adults, as well as children, need the nutrients found in milk. It is the best and most reliable single source of calcium, which is needed by everyone. Milk is recommended for adults because it provides nutrients needed for maintenance of bones and teeth and for other body functions, such as normal clotting of the blood in healing, and regularity of the heart action. Milk is also a valuable source of good quality protein, riboflavin, and many other nutrients.

2. False. Reliable studies show that a reducing plan including a well-balanced breakfast is more successful than one which omits breakfast. The individual feels better, has less fatigue, is more alert, less hungry and less tempted to "nibble" before lunch time. Everyone, including "weight-reducers," needs to replenish the body with vitamins, minerals and protein, as well as energy, after a 10- to 12-hour fast. Surplus body fat can supply some of the energy, but not the other nutrients.

3. True. Because of its high content of protein, calcium and riboflavin, whole or skim milk usually should be included in any diet, reducing or otherwise.

4. False. No single food supplies all nutrients needed by any one part of the body.

5. False. Toasting does not reduce the number of calories. Toasting does slightly reduce the water content, and so weight for weight, a pound of toast actually has a few more calories than a pound of untoasted bread.

6. False. Margarine and butter have the same caloric value. Vegetable oils, from which margarine is made, have the same caloric content as animal fat.

7. False. There is no evidence that any food will either cause or cure this disease.

8. False. Citrus fruits are acid in their original state. After digestion and final use by the body cells, fruits are changed in chemical form and leave an alkaline residue in the blood and tissues. The body needs both acid-forming and alkaline-forming foods, which a mixed diet will supply.

14381

9. False. The only way milk may cause constipation is for a person to take it in such large quantities that he does not eat enough of other foods to give him the necessary bulk.

10. False. Grapefruit contains sugar, vitamins, minerals, and citric acid. None of these in any way removes or helps to remove fat from the body. Although grapefruit is not as high in caloric value as some fruits, it does contain calories.

11. False. Generally speaking there is very little difference in the caloric value of regular white bread and dark bread. Some dark breads containing raisins or made with molasses may have a few more calories than plain white bread.

12. True. Yes, they do. Fruit juices contain the natural sugars of the original fruit and may have sugar added before canning or freezing. A 6-oz. glass of orange juice contains 80 calories; if sweetened, it may have 100 or more.

    Vegetable juices contain fewer calories than unsweetened fruit juices but do contain some: 1 cup of tomato juice contains 50 calories, and if sweetened may contain as many as 75 calories.

13. False. Poor soil reduces yield rather than nutrient content of the food. Furthermore, people are not likely to eat food grown in only one type of soil. The various soil deficiencies here and there will not affect the average person.

14. False. It is safe to keep food in the original can after it has been opened. It is important to cover the can and to keep the food cool. A few acid foods may dissolve a little iron from the can, but this is not harmful or dangerous to health.

15. False. These so-called miracle foods have no unique virtues, no magical powers. Certain special foods, such as wheat germ, brewer's yeast, and blackstrap molasses, do contain a generous amount of some vitamins and minerals or other nutrients. But these nutrients are also found in many common foods and often in a more palatable form.

14381

14382

FOOD NEEDS OF FAMILY MEMBERS

Lesson 3: SIZES OF SERVINGS

PURPOSE

Trainer agent to help aides:

1. Learn what constitutes a standard serving of common foods in each of the four food groups.

2. Learn the importance of amounts served.

PRESENTATION

- Have a bowl of cooked vegetables and paper plates available. Ask each aide to place a serving of a cooked vegetable on a plate. Measure the amount on each plate and compare this to a 1/2 cup standard serving.

- Review the Daily Food Guide. Ask aides to name a food group and tell the number of servings needed for adults and children, and the major nutrient in it.

- Give the following demonstrations:

  - Milk Group. Have various sizes of glasses and cups available. Pour liquids from glasses and cups into a standard measuring cup to illustrate difference in amounts. Exhibit the recommended servings for children, teenagers, and adults including pregnant women and nursing mothers.

    -- Show standard servings from the milk group:

    1 cup milk
    1/2 cup custard
    1/2 cup ice cream
    1/2 cup cottage cheese
    1 cup cocoa (made with milk)
    1 slice cheddar cheese (1 oz.)

14383

-- Exhibit a suggested day's intake from milk group.

- Meat group. Show standard servings from the meat group:

  2 and 3 ounces of cooked meat
  Foods which contain an equivalent amount of protein
  - 4 tablespoons peanut butter
  - 2 eggs
  - 1 cup cooked dry beans or peas

-- Exhibit a suggested day's intake from meat group.

- Fruit and vegetable group. Show standard servings from fruit and vegetable group:

  1/2 cup cooked or raw vegetables or fruit
  1 medium banana, apple, or orange
  1 medium potato
  1/2 grapefruit

-- Exhibit a suggested day's intake from fruit and vegetable group, including fruits and vegetables high in Vitamin A and Vitamin C.

- Bread and cereal group. Show standard servings from bread and cereal group:

  1 slice bread
  1 biscuit or roll
  1 ounce ready-to-eat cereal
  1/2 to 3/4 cup cooked cereal, grits, rice, macaroni

-- Exhibit a suggested day's intake from the bread and cereal group.

. Illustrate serving sizes for children. Two or three tablespoons make a serving for small children.

. Point out people should eat the size of serving they want. Serving size helps us judge the amount of food that is indicated by the Daily Food Guide.

. Discuss the value of teaching serving sizes to homemakers. Include these factors:

  - weight control
  - economy
  - nutritive value and variety.

- Have aides illustrate sizes of servings for adults and children.

- At the end of the lesson have aides place a standard serving of vegetable on a plate and compare with their serving selected at beginning of lesson.

APPLICATION OF LESSON BY AIDES

Aides understand the importance of learning the average sizes of servings from the food groups.

Aides will teach serving sizes when helping homemakers with food preparation.

14385

FOOD NEEDS OF FAMILY MEMBERS

Lesson 4: DIGESTION AND ABSORPTION OF FOOD

PURPOSE

Trainer agent to help aides:

1. Have a basic understanding of how foods are digested by the body.

2. Learn some factors that influence digestion and absorption of food.

PRESENTATION

. Introduce lesson by explaining that food must be changed by the body to become part of your cells and you. Protein, carbohydrates, and fats are broken down into smaller substances in a process called digestion. Show slides 1-13 of "How Food Becomes You" slide set to illustrate. Have aides refer to How Your Body Uses Food, National Dairy Council.

. Show a diagram of the digestive organs. Discuss how food changes in the mouth, stomach, small intestine, and large intestine.

. Point out these facts when discussing digestion in the mouth:

- Digestion begins in the mouth when food is mixed with saliva.

- Saliva contains a digestive enzyme which changes some of the carbohydrates (starch) into sugar. This process is aided by eating slowly and chewing food well.

- Other food is broken up by the teeth into smaller pieces so it can be digested further along the digestive tract.

14385

14386

UNIT 5 - PREPARATION FOR EMPLOYMENT

Competencies

- Identify sources of employment.
- Show a positive attitude toward work.
- Follow acceptable practices when preparing for and during a job interview.
- Manage efficiently personal time, energy, and skills during working hours.
- Communicate effectively with others.

Motivating Procedure

Invite a new employee to discuss his satisfactions in being a part of the world of work.

Learning Experiences

- Invite local employers and an employment service representative to serve on a panel to discuss such topics as where to look for a job, how to apply for a job, conduct during an interview, and what the employer looks for in an applicant.
- Show trainees sample job application blanks using the opaque projector. Discuss unfamiliar terms and the information required. Give trainees job application blanks to complete. Conduct mock interviews with trainees and discuss the impressions made by the applicants and ways these impressions may be improved.
- Present case studies which illustrate situations where the attitudes or values of the employee influenced the action of the employer. Ask trainees to suggest the proper employee action and attitude for each situation.
- Ask trainees to collect newspaper advertisements of jobs related to garment alteration. Discuss qualifications in relation to trainee skills.

Instructional Materials

- Job application forms
- Case studies
- Newspaper advertisements

1436

- Discuss digestion in the esophagus. Food passes through the esophagus to the stomach.
- Explain the steps of digestion in the stomach:
  - The stomach wall contains many muscles which further mix food. The food is churned and partially digested.
  - Enzymes and a mild acid change proteins into smaller, more soluble parts.
  - The churned mass becomes a thick liquid and is passed from the stomach into the small intestine.
- Discuss digestion in the small intestine:
  - Fats are broken down into fatty acids and glycerol. They are absorbed through the intestinal wall into the bloodstream.
  - Partially digested proteins are changed into amino acids.
  - Partially digested carbohydrates (starches) are converted to simple sugars.
  - Amino acids and simple sugars are also absorbed through intestinal walls into the bloodstream.
- Explain the need for protein, carbohydrates, and fat in a balanced diet. Include the following information:
  - Carbohydrates provide quick energy.
  - Proteins build and repair cells.
  - Fat contributes energy and satiety value.
- Explain the steps of digestion in the large intestine:
  - The body cannot digest some substances, such as cellulose. This roughage and other waste products pass through the large intestine and out the body.

14389

FOOD NEEDS OF FAMILY MEMBERS

Lesson 5: SPECIAL DIETS AND HOW TO HANDLE THEM

PURPOSE

Trainer agent to help aides:

1. Know sources of help for persons with special diets.

2. Understand procedures to be followed in helping families with special diets.

PRESENTATION

. Contact a local public health worker, dietitian or physician who is qualified to give aides information about special diets.

. Ask resource person to:

- Lead a discussion on understanding the nature of selected special diets, such as diabetic, low-salt, and cholesterol. Include overall principles of dietary treatment and kinds of foods that need to be altered or avoided in the diet.

- Stress that each special diet is different so the physician's recommendation must be followed.

- Respond to questions aides are often asked by homemakers, such as:

  Johnny is a diabetic, but he eats lots of candy. What should I do?

  Susie is on a special diet but fixing all that special stuff is too much trouble.

  Timmy is allergic to wheat, but I don't know what to do.

14390

14383

- Discuss local agencies and other sources of information on special diets.

- Present the following guides for assisting with special diets:

  - Reemphasize that the aide should only reinforce the diet given by the physician.

  - Remind aide to check with supervising home economist before helping homemaker on a special diet.

  - Ask aides to tell of special diet problems they have encountered.

APPLICATION OF LESSON BY AIDES

Aides encourage families to follow physicians' advice for special diets and obtain help from proper sources.

Aides give out appropriate leaflets to homemakers.

REFERENCES FOR TRAINER AGENT

1. Introduction to Nutrition, Fleck & Munves, (1962) Chapter 30.

2. Facts About Diabetes, ADA Forecast, Cookbook for Diabetics, American Diabetes Association, Inc.

14391

FOOD NEEDS OF FAMILY MEMBERS

Lesson 6: WEIGHT CONTROL

PURPOSE

Trainer agent to help aides:

1. Understand that body weight can be controlled by a balance of activity and food intake.

2. Identify the factors which contribute to overweight.

3. Become aware of the dangers of obesity.

4. Understand that all foods contribute calories to the diet in varying amounts.

PRESENTATION

. Show the slide set "The Oopsies."

. Discuss with aides:

- How many homemakers they visit would they consider to be grossly overweight. (A person who exceeds a desirable weight by 10 percent is considered overweight.)

- Approximately 40 percent of persons in the United States above 40 years of age are believed to be obese. (A person who exceeds his desirable weight by more than 20 percent is considered obese.)

- Children and adolescents who exceed 10 percent of their desirable weight are considered overweight and those who exceed their desired weight by 20 percent are considered obese.

- Discuss these factors which cause homemakers to be overweight or obese:

  - eating because they are bored or frustrated
  - eating too many high calorie foods
  - lacking exercise--refer to pages 3 and 4, Food and Your Weight
  - cultural food patterns
  - habitual eating pattern (developed in youth)
  - heredity
  - social eating
  - metabolic abnormalities (very small percentage of overweight is due to glandular disturbances)

- Ask aides to identify some of the problems related to obesity, such as:

  - difficulty in performing everyday activities--walking, climbing stairs, bending over, etc.
  - more frequent subjection than others to cardio-vascular diseases, diabetes
  - surgery more hazardous
  - pregnant women more prone to toxemia; more complications in delivery
  - higher mortality rate
  - physical appearance less attractive
  - more difficult to find jobs
  - social opportunities more limited

- Review the Daily Food Guide, pointing out that:

  - The minimum number of servings recommended by the Daily Food Guide will supply approximately 1200 calories, which would be a safe reducing diet for most women.

14393

- Show aides how to use calorie tables and serving sizes in booklet, Calories and Weight. Demonstrate calories in servings of common foods.

- List and discuss suggestions for reducers. Use as references Calories and Weight and Food and Your Weight.

- Emphasize these points:

  - Check with doctor first.

  - Take it slowly--a loss of one or two pounds a week is enough.

  - Plan meals around familiar foods.

  - Establish a pattern of eating that can be followed when desirable weight is attained.

  - Do not skip meals.

  - Follow a reliable food plan to be sure that meals are nutritionally adequate.

  - Choose lower calorie foods within each food group.

  - Season foods with spices, herbs, vinegar or tart fruit juices instead of fats, gravies, and other high calorie dressings.

  - Eat cereals or fruit without sugar.

  - Drink coffee and tea without sugar or cream.

  - Budget your calories to take care of special occasions.

  - Choose snacks wisely.

  - Keep busy to avoid eating foods not included in planned meals and snacks.

  - Take more exercise.

14394

APPLICATION OF LESSON BY AIDES

Aides encourage overweight individuals to lose weight by following the Daily Food Guide.

14395

FOOD NEEDS OF FAMILY MEMBERS

Lesson 7: FOOD NEEDS OF INFANTS

PURPOSE

Trainer agent to help aides:

1. Understand the nutritional needs of infants.

2. Learn kinds and amounts of foods needed by infants.

3. Learn ways to help homemakers prepare food for infants.

PRESENTATION

- Discuss milk as a baby's first food. It contains nutrients which infants need for growth and development--protein, vitamins, calcium and other minerals. It also supplies food energy. By the time a child is one year old, he should be consuming foods from all four food groups in a 3- to 5-meal-a-day pattern.

- Enlist the help of a public health nutritionist, nurse or other qualified person to discuss infant feeding:

  - bottle vs. breast feeding
  - methods of bottle sterilization
  - additional nutrient needs of infants
    - liquid
    - vitamin and mineral supplements
  - introducing solid foods to infants
  - weaning the baby
  - coping with feeding problems

- Have aides prepare several foods suitable for feeding infants at different stages of growth:

  - diluted orange juice
  - pureed vegetables
  - mashed fruits
  - strained meats
  - egg yolk

1437

- Have aides practice bottle sterilization procedures.

- Discuss community agencies, clinics, and resources providing information and help for mothers with infants --for example, well-baby clinics.

APPLICATION OF LESSON BY AIDES

Aides understand principles of infant feeding.

Aides teach homemakers how to prepare food for infants.

Aides teach homemakers importance and methods of sterilizing equipment for feeding infants.

Aides inform homemakers of community resources available.

14397

FOOD NEEDS OF FAMILY MEMBERS

Lesson 8: FOOD NEEDS OF THE PRESCHOOL CHILD

PURPOSE

Trainer agent to help aides:

1. Understand the nutritional needs of the preschool child.

2. Know the kinds and amounts of food needed by preschool children.

3. Learn to help homemakers plan meals to meet the food needs of preschool children.

PRESENTATION

- Show slides 1-35 of "Feeding Young Children." Discuss the following:

  - Preschool children need the same foods as adults but in different amounts. Refer to the Daily Food Guide. Emphasize the recommended intake of the milk group in particular.

  - The growth rate is slower during the preschool years than during infancy. However, there is a continuous need for a well-balanced diet.

  - The amount of food a preschool child needs depends on age, rate of growth, size, and activity.

- Review with aides Lesson 7, Feeding Young Children from Food and Nutrition--Basic Lessons, and section on young children in Food, A Key to Better Health.

- Illustrate a possible meal pattern for a good daily diet for a preschool child. Stress sizes of servings for preschool children. Demonstrate appropriate serving sizes.

14398

- Discuss the importance of regular meals for preschool children. Children have small stomachs, and therefore may not be able to eat enough food at a meal to last for a long period. In addition to regular meals, snacks play an important role in the diet of a preschool child.

- Discuss nutritious snacks for children. Have aides suggest foods from the illustrated meal pattern that would be good snacks for preschool children. Suggest other foods that would provide valuable nutrients, rather than just empty calories.

- Ask aides to list some problems of homemakers in feeding preschool children. Have aides relate these problems to characteristics of this age group. Discuss how these problems can be handled.

APPLICATION OF LESSON BY AIDES

Aides prepare a low cost nutritious meal appropriate for a family with young children. Show how this meal can be adapted for a preschool child.

Aides help parents understand the importance of helping their children establish good food habits.

14400

FOOD NEEDS OF FAMILY MEMBERS

Lesson 9: FOOD NEEDS OF SCHOOL CHILDREN

PURPOSE

Trainer agent to help aides:

1. Understand food needs of school-age children (6 to 12 years).

2. Know the types and amounts of foods they need.

3. Learn more about the kinds of food programs available for them.

PRESENTATION

. Discuss characteristics of this age group which affect nutrient needs and food habit formation:

- From ages 7 to 10, growth usually is steady. For girls, growth is usually more rapid around 10 to 11, and for boys the growth spurt begins about 13 to 15.

- Nutrient needs are still high and calorie needs are increasing to provide building material for growth, furnish energy for vigorous physical activity, help maintain resistance to infection, and develop an adequate store of nutrients for growth and stresses during adolescence.

- Until age 9, boys and girls have similar nutrient needs. After 9, boys need more calories than girls because they are usually more active. Ask aides to identify and compare activities of boys and girls from 9 to 12 years old.

14401

S0001

- Emphasize that school children still look to adults for guidance:

  - Children, even though in school, need an example set for them at home to form good food habits. Have aides discuss ways that parents can set a good example.

  - Teachers and "heroes" may be influential outside the home in the formation of food habits.

- Point out that children have increasing responsibilities for making own food selections:

  - Changes in community life provide children with opportunities to eat more meals away from home. Have aides identify some of these changes, such as vending machines, school lunch, school breakfast, and day camps.

  - There are fewer chances for the family to be together for mealtime. Mother's work takes her out of the home. Children often have the responsibility for preparing their own breakfast.

  - There is increased snacking without supervision. Have aides discuss ways they can encourage homemakers to have nutritious snacks available in the home.

- Relate the Daily Food Guide to the food needs of the school-age child.

- Discuss the nutrients which need to be especially emphasized for the school-age child, using as a guide the USDA Food Consumption Studies in Food For Us All, pp. 269-270. Ask aides to identify snack foods for school children which would be high in these nutrients.

- Discuss school feeding programs using Food For Us All, pp. 73-74, 260-264, and 298-299, as a guide.

- Ask a school lunch supervisor to discuss the following points with the aides:

  - food requirements for participation in the National School Lunch Program or School Breakfast Program.

  - eligibility of children for free or reduced-price lunches or breakfasts.

  - attitudes of children toward the school lunch program.

14402

- List on the chalkboard the foods and amounts included in a school breakfast or school lunch. Have aides plan food for the remainder of the day to meet the recommendations in the Daily Food Guide. Collect school lunch menus printed in daily newspapers and have aides plan remaining meals and snacks for a day for a school-age child.

- Have aides use comparison cards to answer questions such as:

  My daughter won't drink orange juice; what should I do?

  My son doesn't drink milk, but he eats lots of ice cream; isn't that all right?

  Why do we often hear,"serve liver to your children"?

  My children love peanut butter and jelly sandwiches; is this all right?

APPLICATION OF LESSON BY AIDES

Aides encourage homemakers to consider the school lunch in planning food for the other meals and snacks.

Aides become alert to those who are eligible for free or reduced-price school lunches or breakfasts.

Aides encourage participation in school food programs where possible.

Aides encourage parents to set a good example for children in selecting nutritious food for meals and snacks.

REFERENCES FOR TRAINER AGENT

14404

FOOD NEEDS OF FAMILY MEMBERS

Lesson 10: FOOD FOR THE TEENAGER

PURPOSE

Trainer agent to help aides:

1. Understand food needs of teenagers.

2. Understand some of the reasons for teenagers' eating habits.

3. Develop techniques and methods to reach teenagers with nutrition information which may encourage them to make wise food choices.

PRESENTATION

- Review the four food groups and discuss different patterns of eating. Emphasize that it is the amount and kind of food eaten within a 24-hour period that counts and not just what is eaten at one meal.

- Show the slide set entitled "Improving Teenage Nutrition." Discuss social, emotional, and physical needs of teenagers and how these needs may affect their eating habits.

- Emphasize that:

  - Adolescence is an age of great activity.

  - It is period of rapid growth.

  - Eating snacks is a way of life for a busy teenager.

  - Many physical and emotional changes take place during adolescence.

  - Some foods, such as milk, are considered baby foods; others, like coffee, are grown-up foods. Refer to pages 299-301, 273-278, 1969, Yearbook of Agriculture <u>Food for Us All</u>.

00441 14405

- Have aides suggest ways of providing nutritious foods for teenagers to fit their pattern of eating. List all suggestions on newsprint or chalkboard under nutrient headings.

- Review survey findings, using the charts provided in this lesson as a guide. What foods can be added, and how, to insure adequate intake of needed nutrients?

- Divide the aides into groups. Give each group a copy of A Girl and Her Figure and A Boy and His Physique. Ask them to talk over what they would emphasize to interest teenagers in wise eating practices. Have them report back to the total group.

- Have each aide tell the group how she plans to help homemakers understand why teenagers need to know how to make wise food choices.

APPLICATION OF LESSON BY AIDES

Aides help homemakers and teenagers understand the importance of eating a wide variety of foods.

14406

UNIT 6 - MANAGEMENT OF A GARMENT ALTERATION BUSINESS

Competencies

- Organize business and work area for efficiency and comfort.
- Plan work schedule effectively.
- Purchase and inventory sewing equipment and supplies.
- Maintain accurate financial and customer records.
- Analyze the cost of time and supplies required for an alteration.

Motivating Procedure

Present the findings of a local survey of charges made for various garment alterations. Discuss the reasons for any variation in prices.

Learning Experiences

- Take a field trip to one or more alteration facilities to observe the organization of the business and work areas, how work is scheduled, and the equipment used. Have students discuss observations in terms of their proposed employment.
- Have each trainee design a floor plan for a clothing alteration business and work area and make a detailed list of equipment and supplies required for this plan.
- Divide class into small groups and have each group interview a manager of some type of an alteration facility to determine the kinds of customer and financial records that are needed. Have students share experiences with the class. See Appendixes M and N.
- Present case studies involving garments needing alteration, including such items as time and supplies required to complete the job. Have trainees figure cost of alteration and fill out customer's bill. Discuss charges made for various alterations.
- Discuss the advantages and disadvantages of having an independent business in a private home, including such topics as convenience, facilities, speed and work standards, and customer relations.
- Have trainees interview dressmakers who have a business of their own to determine how customers are secured. Discuss advantages and disadvantages of such methods of advertising as the newspaper, bulletin board notices in public places, radio announcements, and word of mouth from satisfied customers.

FOOD NEEDS OF FAMILY MEMBERS

Lesson 11: FOOD NEEDS FOR PREGNANT AND LACTATING WOMEN

PURPOSE

Trainer agent to help aides:

1. Become familiar with nutritional needs of pregnant and lactating women.

2. Learn about resources in the community where a mother can receive care for herself and her baby.

3. Learn how to help pregnant and lactating homemakers add additional foods to family meals to meet their requirements.

PRESENTATION

. Ask a qualified local public health worker to discuss:

- services available at local health department for pregnant and lactating women.

- the importance of good nutrition before and during pregnancy.

- increased food needs for mothers who breast feed their babies.

- individual differences in relation to pregnancy such as nausea, rate of weight gain, constipation, edema.

- questions aides may have encountered or wish to ask.

14410

Outline general guidelines for working with pregnant women:

- Every pregnant woman should eat the kinds and amounts of food recommended by the Daily Food Guide or the diet prescribed by her physician.

- In the early months of pregnancy the baby is very small and extra food is not needed.

- In later months the baby grows rapidly. To meet these extra growth demands the mother should have more food from the four food groups. At least 3 cups of milk a day is desirable.

- The teenage pregnant girl is going through two growth cycles--her own and her baby's. She should have foods sufficient to cover both growth needs.

APPLICATION OF LESSON BY AIDES

Aides help pregnant homemakers plan adequate diets.

Aides understand food needs of pregnant and lactating women and refer mothers to agencies which can help them.

FOOD NEEDS OF FAMILY MEMBERS

Lesson 12: FOOD NEEDS OF THE ELDERLY

PURPOSE

Trainer agent to help aides:

1. Understand the nutritional needs of older persons.

2. Identify some of the special problems that influence eating habits of the elderly.

3. Become aware of community agencies which may be helpful to older folks.

4. Assist the aging to make good food choices and to avoid food fads.

PRESENTATION

- Review the Daily Food Guide and relate it to the food needs of the elderly.
- Emphasize in your discussion that:

  - Older persons often need to be encouraged to eat a wider variety of foods. Ask aides to identify foods which seem to be popular and foods which are not generally eaten by the elderly with whom they visit. To which food groups do these foods belong?

  - Selection of foods from the four food groups will discourage food faddism to which many older persons are susceptible. Discuss briefly some of the reasons older persons may be particularly vulnerable to food faddism.

14413

- Fewer calories are needed because activity is less. Ask aides to describe the types of activities they observe in homes of older people and to compare these to activities in homes of young families. Have aides identify ways in which calories may be limited within each of the four food groups.

- Physiological changes may also call for some modification of diets.

. Discuss factors which influence food habits of the elderly. List on board as they are brought out in discussion.

. Include these points in your discussion:

- Food habits have been formed in earlier years.

- Some foods may cause physiological distress.

- Lack of proper dentures may limit food choices.

- Eating alone may make eating less enjoyable.

- Food preparation may be hindered by physical disabilities, lack of equipment and facilities for serving and storing food.

- Illness, disability and lack of transportation can make food shopping difficult.

- Income may be limited.

- Some elderly persons may be confused by the variety of items in stores.

. Have aides role-play a visit to the home of an elderly man who lives alone, whose income is limited and who walks with crutches. Help him plan food for a day.

. Have aides plan food for a day for an older person without dentures.

. Introduce Food Guide for Older Folks and Lower Cost Meals that Please. Discuss content.

. Explore available community resources for improving the nutrition of older persons living alone. Prepare a list of these for the aides.

14414

- Discuss:

  - What available educational programs relate to planning meals and to selecting, buying and preparing food?

  - What meal assistance programs are available through community agencies?

- Ask a representative from an agency that deals with some of the problems of older persons in your community to discuss the role of the agency, how it functions, the services it provides and how these services can be made available to those who need them. Allow time for aides to ask questions.

APPLICATION OF LESSON BY AIDE

Aides apply this information in teaching families with elderly members as well as older persons living alone.

ABSTRACT - This booklet is one in a series of booklets of supplemental lessons in food and nutrition prepared by the Extension Service of the U.S. Department of Agriculture and is designed for use by trainer agents in on-the-job training of Extension aides to provide them with information about nutrients and with teaching methods to use in helping families. Purposes, presentation suggestions, learning activities, references, audiovisual materials, and equipment accompany these lessons: (1) Protein, (2) Carbohydrates, (3) Fat, (4) Calcium, (5) Iron, (6) Iodine, and (7) Vitamins A, B, C, and D. An introductory section provides additional suggestions for the trainer agent and lists recommended references. Related booklets are available as VT 012 840-VT 012 843, all in this issue. (SB)

Lesson 10: Vitamin D 38

Key Nutrients is one of a series of booklets of supplemental lessons in food and nutrition, designed for use in on-the-job training of Extension aides. These lessons are not intended to be complete teaching units. The purpose is to enrich the aides' background in food and nutrition and to provide practical teaching methods that they can use in taking food and nutrition information to families. Since technical subjects in nutrition are simplified some of the generalizations may have exceptions.

FOOD AND NUTRITION

Supplemental Lessons for Training Extension Aides

KEY NUTRIENTS

Purpose

These lessons were written to help trainer agents further prepare aides for work with families in the Food and Nutrition Education Program. It is the responsibility of the trainer agent to see that aides have a broad perspective of the importance of food to people, a basic understanding of nutrition and an understanding of how to teach this information to low-income families.

The series follows the 15 basic lessons in nutrition given in the initial training for aides and leaders and will help the trainer agent enlarge the background nutrition knowledge of the aides. The series is an expansion of Lesson 3 - Key Nutrients from Food and Nutrition--basic lessons for training Extension aides and should be applied to the problems the aides have identified. The information may be used by the aide as the occasion arises in her work with families and the lessons adapted by the aide for use with groups of youth or adults.

TRAINER AGENT'S RESPONSIBILITY

References are suggested for the agent's use with each lesson. The agent will find it helpful to assemble these references before starting the lessons and to use them in her preparation for teaching.

References are also suggested for the aide's use. The agent should be selective in the references she gives to aides. Order those selected well in advance.

Go over references thoroughly with the aides so that they know what is in each reference.

Professional people in related fields may be asked to participate in training meetings. Such participation should be planned well in advance.

14420

A working relationship with each aide should already be established as a result of the initial training period. Effective communication remains vital in teaching. Before teaching supplemental lessons, the trainer agent may wish to review purposes of the training and the importance of aides' participation.

Suggested check list to be sure that all necessary preparations for the in-service training sessions have been made:

___Meeting place with necessary facilities has been obtained.

___All references needed to complete the lessons have been assembled.

___Local public health service and library have been checked for additional references.

___All visual materials and equipment needed to teach the lessons are on hand.

___All reference materials needed for the aides have been obtained.

___All lesson plans have been carefully studied so that you fully understand the overall content of the course.

___Sufficient time has been allowed to complete each lesson.

ADAPTING THE LESSONS TO YOUR AIDES

Guides used in teaching the basic lessons should be followed in teaching the supplemental lessons also:

Adapt training classes to meet the needs of your group. Here are some ideas to keep in mind:

1. Simplify. Do not try to cover too much material in one lesson. Pick out the most important points and emphasize these.

2. Use colorful visuals and a dynamic presentation to help make the lesson more appealing.

3. Emphasize good nutrition elements in the food the aides are now eating. Point out how small changes can often result in a more balanced diet.

4. Involve the aides in the training meetings in as many ways as possible.

EXTENDING INFORMATION

The information given in the supplemental lessons may be effectively used in other ways, such as adaptation for use in training volunteer leaders or in newsletters or newspaper article. A series of radio or TV programs based on the lessons may help to extend to a larger audience the ideas that aides are promoting.

14422

Recommended publications

For aides and leaders

Publications and visual materials are listed with each lesson. Make sure that these supplies are on hand before you begin teaching.

USDA

Bulk quantities of USDA pamphlets are usually obtained through your State distribution officer.

Family Fare, G-1
Milk in Family Meals, G-127
Nutritive Value of Foods, G-72
*Key Nutrients, PA-691 (5¢)
*How Food Affects You (flipchart in booklet form) 1970. 32 pages. (60¢)
*Composition of Foods, Agricultural Handbook No. 8. $1.50.
*Daily Food Guide Leaflet, F&NS-23 (35¢ for 10 copies)
Food for Thrifty Family flyers, F&NS
Free illustrated F&NS flyers and the Daily Food Guide are available for educational programs relating to U.S. Department of Agriculture's Family Food Assistance Programs through your regional Food and Nutrition Service office.

HEW

The Food You Eat and Heart Disease, No. 537

Copies of publications from Department of Health, Education and Welfare may be obtained locally from the Public Health Service or purchased from the Superintendent of Documents.

*Publications NOT available free may be purchased from Superintendent of Documents, Government Printing Office, Washington, D.C. 20402, at the prices indicated. There is a 25 percent discount for 100 or more copies on all GPO orders.

14423

Recommended references

For trainer agents

Each lesson includes a list of recommended reference books and publications for trainer agents to use in preparing lessons. Make sure you have the references you need to do a good job.

Eat to Live, Wheat Flour Institute, 14 E. Jackson Blvd., Chicago, Ill. 60604. 1969. $1.00.

Principles of Nutrition, Wilson, Eva D. and others; John Wiley and Sons, Inc., 605 3rd Ave., New York, N.Y. 10016. 1965. $8.50.

Teaching Nutrition, Eppright, E. and others; Iowa State Press, Ames, Iowa 50012. 1963. $4.95.

14424

Visuals

Slide Sets

"How Food Affects You," C-156. 1969. 48 frames. $8.00.
"Milk the Magnificent," C-161. 1969. 50 frames. $8.00.

USDA slide sets may be purchased from the Photography Division, Office of Information, U.S. Department of Agriculture, Washington, D.C. 20250.

Charts and Posters

How Food Affects You (flip chart in booklet form). 1970. 32 pages color. 60¢. Superintendent of Documents.

*Daily Food Guide Poster, 22" x 28". 15 cents per copy.

National Dairy Council

Comparison Cards for Adults. B-43-A. $2.50 a set.
Food Models B-12. $3.00 a set.
Display for Food Models. G-100. $1.50.
Milk Made the Difference. Poster P-512. 30 cents.

A catalogue can be obtained listing available materials. If you live in a city where there is an affiliated Dairy Council Unit, requests for material should be directed to that office. If you are not served locally, send orders to National Dairy Council, 111 North Canal Street, Chicago, Ill. 60606.

Wheat Flour Institute

Wall chart on Wheat Kernels.

14425

KEY NUTRIENTS

Lesson 1: PROTEIN

PURPOSE

Trainer agent to help aides:

1. Learn how the body uses protein.

2. Learn food sources of protein.

3. Learn the importance of and methods for supplementing vegetable protein with animal protein.

PRESENTATION

- Review lesson 5 of Food and Nutrition---basic lessons for training extension aides by discussing the concept that foods may be classified as protein, carbohydrates, and fats. Most foods are a combination of nutrients. Vitamins, minerals and water are found in combination with these classes of food.

- Have aides identify parts of their body which are made of protein. You can see some of these parts--muscles, skin, hair, nails, eyes. Much of what you do not see is also made of protein--blood, heart, nerves, brain and others.

- Show aides how to use visuals in teaching the function of protein in the body. Use charts 4-8 from the booklet "How Food Affects You" or slides 16 and 17 of the set with the same title. Explain that protein:

  - Builds and maintains all tissues.

  - Forms an important part of enzymes. Enzymes are substances that break our food down so that it can be digested and used in the body.

  - Forms an important part of many hormones. Hormones regulate body processes.

14426

The Local Course of Study

The advisory committee and administrative staff can provide assistance relative to job opportunities for which training should be provided, course content, organization, and resources for the instructor. Suggestions for organizing and presenting a local course in the area of garment alterations are given in this section.

ORGANIZING A LOCAL COURSE

The local course of study should be based on the State outline. The following will help to provide a well organized local plan.

- Determine the length and units for the course from the chart Time Allocations for Course Units, found on the following page, by:
  - Identifying jobs for which the course will be designed
  - Selecting units and topics to be covered
  - Estimating time needed for course. For example, training for the job of dressmaker requires 84 hours and could be scheduled for two weeks for six hours a day or fourteen weeks for two, three hour sessions a week.

- Adjust and develop the materials given in the State course to meet local needs.

PLANNING A LESSON

It is the instructor's responsibility to prepare thoroughly for each class session. He must have full knowledge of the concepts and skills he will teach. A lesson can be planned to be completed in one session or extended over several class sessions. The following points may serve as guidelines for planning a lesson.

- Teach one thing at a time.

- Proceed from the simple to the complex.

- Prepare lesson content to meet needs of trainees.

- Make the practice experiences interesting and fruitful.

- Prepare for the class session by studying the lesson plan and collecting the required teaching materials such as audiovisual aids and equipment, instructional materials for distribution to trainees, books and other resources related to the lesson, and sewing equipment and supplies for demonstrations or trainee use.

- Forms an important part of body fluids. Next to water, protein is the most plentiful substance in the body.

- Supplies energy.

. Have aides identify food sources of protein. Use food models to group proteins into animal and plant sources:

Animal Sources	Plant Sources
lean meat	dry beans
poultry	peas
fish	nuts
seafoods	cereals
eggs	breads
milk	
cheese	

. Point out which of the four food groups contribute protein to the diet and which group makes the greatest contribution of protein. Refer to Daily Food Guide.

. Include these points in your discussion:

- Animal sources of protein are of better quality than plant sources.

- Protein is made up of smaller parts called amino acids. These are referred to as the building blocks of protein.

- Some amino acids can be made in the body from other amino acids. However, some amino acids cannot be made in the body, and therefore must be supplied in food. These are called essential amino acids.

- Animal protein sources contain more of the essential amino acids needed to build cells for the human body than plant protein sources do. Because animal protein has more amino acids needed by the body, it is of better quality than plant protein.

14427

14426

- Plant protein eaten in combination with a small amount of animal protein improves the nutritional value of the diet.

- Use the Daily Food Guide to illustrate the recommended number of servings of meat or meat alternates. Point out that protein foods should be eaten throughout the day so that the essential amino acids may be most effectively utilized in the body. Explain that protein eaten in excess of body needs will be converted to fat in the body.

- Have aide list protein foods she eats. Have the aide suggest animal protein foods that can be eaten in small amounts in combination with those foods that are vegetable protein to improve the nutritional quality such as:

  - cereal and milk

  - beans and cheese

  - beef and rice

APPLICATION OF LESSON BY AIDES

Aides help homemaker recognize that there are many protein foods in addition to meat. Protein is supplied from vegetable sources and only small amounts of animal protein need be added to improve the quality.

Aides suggest combinations of animal and vegetable protein foods to homemakers.

Aides encourage homemakers to eat some protein foods at each meal.

14429

14429

KEY NUTRIENTS

Lesson 2: CARBOHYDRATES

PURPOSE

Trainer agent to help aides:

1. Learn how the body uses carbohydrates.

2. Learn food sources of carbohydrates.

3. Understand the significance of empty-calorie foods.

PRESENTATION

- Review lesson 5 of Food and Nutrition---basic lessons for training extension aides by discussing the concept that all foods may be classified as protein, carbohydrates, and fats, and that all supply energy in varying amounts. Vitamins, minerals and water are found in combination with these classes of food.

- Show aides how to use visuals in illustrating the function of carbohydrates in the body. Show slides 32-33 from "How Food Affects You" or chart 28 from the flip charts. Emphasize that carbohydrates:

  - Supply food energy.

  - Help the body use fat efficiently.

  - Spare protein for purposes of body building and repair.

- Point out that carbohydrates are made up of sugar and starches. A starch is a complex made up of units of sugars.

14431

14430

- Illustrate the food sources of carbohydrates using food models:

Sugars	Starches
honey	breads
molasses	cereals
syrup	corn
sugar	grits
	potatoes
	rice
	spaghetti
	macaroni
	noodles

- Point out the food groups that make the largest contribution of carbohydrates. Refer to the Daily Food Guide.

- Include these points in your discussion:

  - Carbohydrates are the main source of energy for the peoples of the world because they are found in plentiful and economical foods.

  - Many carbohydrate foods are empty-calorie foods. An example is sugar. Stress eating carbohydrate foods that contain other valuable nutrients.

  - A small amount of carbohydrates is stored in the body. However, if carbohydrates are eaten in great excess of energy needs, the excess will be stored as fat in the body.

- Have aides select several dietary recalls from their lists of homemakers. Evaluate the dietary intake of carbohydrates, watching for the inclusion of important nutrients -- protein, vitamins and minerals -- in the foods also.

APPLICATION OF LESSON BY AIDES

- Aides understand what empty-calorie foods are and how to substitute other nutritious foods for them.

14431

- Aides encourage homemakers to select carbohydrate foods that contain vitamins and minerals.

REFERENCES FOR TRAINER AGENT

14432

KEY NUTRIENTS

Lesson 3: FAT

PURPOSE

Trainer agent to help aides:

1. Learn the function of fat in the diet.

2. Learn food sources of fat.

3. Understand the meaning of polyunsaturated fats.

PRESENTATION

- Review lesson 5 of Food and Nutrition---basic lessons for training Extension aides by discussing the concept that all foods may be classified as protein, carbohydrates, and fats, and that all supply energy in varying amounts. Vitamins, minerals and water are found in combination with these classes of food.

- Discuss the function of fats in the body. Show slides 32-34 from "How Food Affects You" or chart 28 from flip charts, showing aides how to use visuals in teaching homemakers. Emphasize that fats:

  - Supply energy in compact form (weight for weight, fats supply twice as much energy as carbohydrates).

  - Supply some essential fatty acids.

  - Help the body use certain other nutrients. (Fats are carriers of fat soluble vitamins A and D.)

  - Add variety and flavor to many foods.

  - Protect the body from excessive loss of heat.

  - Support and protect vital organs.

14433

- Show a bottle of oil and a can of solid fat. Ask aides if they know the difference in these food items.

  - Both are fats.

  - Oils are liquid fats at room temperature, solid fats are solid at room temperature.

  - Liquid oils are generally made from vegetable sources. Most vegetable oils are highly polyunsaturated. This refers to the type of fatty acids in the oil.

  - Solid fats are predominately made from animal sources and contain mostly saturated fatty acids. However, many times polyunsaturated fats are added to solid fats.

- Have aides read several can and jar labels to see if polyunsaturated fatty acids are contained in the fat or oil.

- Briefly mention research that has shown there may be a relationship between a highly saturated fat (animal) intake and incidence of heart disease. There have been recommendations to increase the proportion of polyunsaturated fats in the diet for people with certain kinds of heart ailments.

- Discuss the function of fats in the body. Show slides 32-34 from "How Food Affects You" or chart 28 from the flip chart.

- Illustrate the food sources of fats using food models, pictures or cartoons:

  fat in meat
  lard
  cooking fats and oils (foods cooked in them)
  butter
  margarine
  salad dressings
  salt pork and bacon drippings

14434

- Point out that normal persons should have some animal and vegetable fat in the diet each day. Fats eaten in excess of body needs are stored as fat in the body.

- Have aides tell how they would teach homemakers the meaning of the term polyunsaturated found on the label from a can of shortening.

APPLICATION OF LESSON BY AIDES

Aides encourage homemakers to select fat foods that also contain vitamins and minerals.

3. Food - A Key to Better Health, Nutrition Foundation, p. 5.

4. Family Fare, G1, USDA, p. 9.

14435

KEY NUTRIENTS

Lesson 4: CALCIUM

PURPOSE

Trainer agent to help aides:

1. Understand how the body uses calcium.

2. Learn the food sources of calcium and ways to get the recommended amounts each day.

PRESENTATION

. Review information, pointing up the need to emphasize calcium in teaching homemakers.

  - Refer to the review of the 1965 Food Consumption Study in Food For Us All, pp. 266-272.

. List on the board, the groups of people who are not likely to get the recommended amounts of calcium in their diets.

  - teenagers
  - adults
  - older folks

. Point out that calcium is a mineral. Minerals help build the body structure and help regulate many processes in the body. Calcium is the substance found in ordinary blackboard chalk, limestone, road rock, sea shells, and bones.

. Discuss the function of calcium in the body. Use illustrations in "How Food Affects You" flip charts, pages 8, 9 and 10, or slides 19 and 20 from series by same title. Ask the aides to review Key Nutrients for a summary of functions and sources of calcium.

14436

TIME ALLOCATION FOR COURSE UNITS

UNITS AND TOPICS	JOB TITLES AND APPROXIMATE HOURS†					
	Garment Ripper	Women's Garment Finisher	Seamstress	Tailor's Helper	Garment Fitter	Dressmaker
Use and Care of Fabrics	6	6	6	6	6	6
Selection, Use, and Care of Sewing Equipment	3*	3*	6	6	6	6
Techniques of Sewing						
• Pressing Techniques	3	3	3	3	3	3
• Construction Techniques	6*	6*	21	21	21	21
• Alteration Techniques			21	21	21	21
• Repair Techniques			9	9	9	9
Elements and Principles of Design					4	4
Preparation for Employment	6	6	6	6	6	6
Management of a Garment Alteration Business						8
Total hours	24	24	72	72	76	84

† Time has been allocated in two and three hour units so that the classes can be taught in evening or day sessions.

* Only selected portions of learning areas will be needed for these jobs.

0441 1441

- Explain that:

  - Calcium is distributed unevenly in the body -- 99% is found in bones and teeth; 1% is found in the fluids and soft tissues.

  - Calcium helps in muscle contraction, nerve transmission, blood clotting, and beating of heart.

- Show pictures of animals from "Milk Made the Difference" and discuss. Show slides 4-12 from the "Milk the Magnificent" slide set. Show aides how to use visuals in working with homemakers.

- Point out that:

  - The best sources of calcium are milk and milk products. It is difficult to supply the amounts of calcium recommended unless milk in some form is used daily.

  - Ask aide to name the major nutrient contributions of the milk group. List them on board or newsprint:
    - calcium
    - protein
    - riboflavin

  - Milk products add variety to meals and snacks and can be used in place of some of the milk which would be drunk. Use comparison cards, food models, or actual food to show these calcium equivalents of one cup of fluid milk:

1 1/3 oz.	cheddar
1 1/3 cups	cottage cheese
1 cup	cocoa made with milk
1 cup	custard
1 1/2 cups	ice cream
3/4 cup	macaroni and cheese

14436

14437

- Show amounts of milk recommended in the Daily Food Guide to help supply calcium:

Children under 9	2-3	8 oz.-cups or equivalent (or more)
Children 9-12	3	" " " "
Teenagers	4	" " " "
Adults	2	" " " "
Pregnant women	3	" " " "
Nursing mothers	4	" " " "

- Discuss other food sources of calcium such as:

  - dried peas and beans
  - collards, kale
  - dandelion, mustard, and turnip greens
  - canned salmon and mackerel
  - enriched breads made with milk or dry milk solids

- Emphasize that young children need calcium because their bones are growing. Older persons need calcium to keep their bones hard and strong.

- Ask aides to review a few of the food recalls from homemakers to evaluate the milk intake.

- Have aides role-play a visit with a homemaker who does not use milk because she believes it is too expensive.

- Have an aide prepare a flavored milk drink using dry milk. Serve this for refreshments. Suggest ways of adding dry milk to foods to increase calcium intake.

14438

- Have aides identify foods that are high in calcium from a list. Look up calcium content in Nutritive Value of Foods G-72 and report back. Suggested list:

  apple
  bacon
  dry beans
  green snap beans
  bread, enriched
  liver
  broccoli
  butter
  cabbage
  carrots
  cream cheese
  chocolate milk
  corn
  clams
  crab meat
  eggs
  ice cream
  skim milk
  oyster stew
  green pepper
  spinach
  canned salmon

APPLICATION OF LESSON BY AIDES

Aides encourage children to drink more milk by teaching their mothers to prepare flavored milk drinks and frozen snacks.

Aides use "How Food Affects You" flip charts and "Milk Made the Difference" pictures with homemakers to teach the importance of the milk group.

14440

KEY NUTRIENTS

Lesson 5: IRON

PURPOSE

Trainer agent to help aides:

1. Understand how the body uses iron.

2. Learn food sources of iron and methods of including iron-rich foods in the diet.

PRESENTATION

. Review the importance of iron and its functions in the body. Emphasize that:

- Iron deficiency is the most prevalent nutritional disorder among children in the United States.

- Iron is a mineral like calcium or iodine that our bodies need to function properly.

- Iron combines with protein in our bodies to form hemoglobin, the red substance in our blood which carries oxygen from the lungs to all parts of our bodies. Body cells must be constantly supplied with oxygen to sustain life.

- Iron forms part of several enzymes in the body. Enzymes are substances that break food down so that it can be digested and used in the body.

- Iron is stored in the liver, bone marrow and spleen in the body.

. Point out that the best sources of iron are:

- liver and other organ meats

- dried peas and beans

14441

- egg yolks

- beef, pork, lamb and veal

. Emphasize that other good sources of iron are:

- enriched or whole-grain breads and cereals

- dark green leafy vegetables

- dried apricots, prunes, raisins

- molasses

. Point out that iron content of some food can be increased by cooking in cast iron utensils.

. Explain that egg yolk is one of the first solid foods added to an infant's diet because milk contains very little iron.

- Menstruating women require larger amounts of iron because of the periodic loss of blood.

- Iron-deficiency anemia, which can cause a tired feeling, is due to a lack of iron in the diet. A physician should be consulted to treat anemia.

. Have several aides use pages 12-14 of the flip chart "How Food Affects You" to discuss with the group how they might use this visual to teach homemakers that iron is a nutrient found in foods that our bodies need to function properly.

. Have aides prepare, or tell how they have prepared, one or two iron-rich foods, such as organ meat, molasses cookies, a dark green vegetable.

. Have aides share with the group how they would help homemakers introduce iron-rich foods into their family diets, such as having raisins available for afternoon snacks; using molasses cookies instead of plain cookies; or adding molasses to baked beans.

. Give aides several menus that lack or are low in foods containing iron. Let them suggest ways to include iron.

14443

208

KEY NUTRIENTS

Lesson 6: IODINE

PURPOSE

Trainer agent to help aides:

1. Understand how the body uses iodine.

2. To learn the food sources of iodine and the importance of using iodized salt.

PRESENTATION

. Review information pointing up the need to emphasize iodine in teaching homemakers. Emphasize that:

- Iodine is a mineral, like calcium and iron, that is necessary for our body. Although large amounts are toxic, small amounts of iodine are important for a balanced diet.

. Discuss the function of iodine in the body:

- Iodine forms part of the hormone thyroxine which regulates body processes. Thyroxine is made by the thyroid gland which is located in the neck. Thyroxine regulates the rate at which the body produces energy from food. If the activity of the thyroid gland is slow, the body tends to store up energy in fat. If the gland is over active, the body burns up food and body reserves too fast and tends to become thin. Both conditions affect physical and mental health, nerves, rate of heart beat and appetite.

- Iodine is necessary for maintenance of body processes throughout life.

14444

- Discuss food sources of iodine, such as:

  - iodized salt

  - shell fish

  - salt water fish

- Point out that the simplest way to be sure there is enough iodine in the diet is to use iodized salt. Ask how many aides use iodized salt. Compare the prices of iodized and regular salt in the local food stores. Show labels from boxes of both iodized and regular salt.

- Explain that some persons cannot use iodized salt because they have certain diseases. For those who are healthy, however, iodized salt is recommended.

- Emphasize that iodine is stored in the thyroid gland in the neck. A simple goiter, which is an enlargement of the thyroid gland, may be caused by insufficient iodine in the diet. Explain that the use of iodized salt is important in the prevention of simple goiter. Ask aides if they have ever known anyone with a goiter.

APPLICATION OF LESSON BY AIDES

Aides understand the importance of using iodized salt.

Aides check at local food stores for iodized salt.

Aides compare cost of iodized and regular salt.

Aides encourage homemakers to choose and use iodized salt instead of regular salt.

14444

14445

- Use teaching aids frequently to enrich the classroom presentation. Use them to help trainees understand a concept or skill. Visual aids may be purchased, borrowed from companies, or made by the instructor. A list of the most common instructional aids include bulletin and flannel boards; shadow boxes; display windows; duplicated aids such as films, filmstrips, film loops, overhead transparencies, and opaque printed material; flip and data charts; and three dimensional aids such as actual parts, mockups, and models.

- Indicate the relation of this lesson to previous lessons and to the job.

- Emphasize the key points to be covered in the lesson.

- Use a variety of evaluative devices to check student progress in relation to job competencies. Some techniques that can be used include score cards, rating scales, progress charts, interviews, objective tests, and written or oral response to case problems.

PRESENTING A LESSON

A successful teacher is one who is aware of the feelings of others and has a contagious enthusiasm for work. He uses a well-modulated voice, is cheerful, courteous, and sympathetic. It is important that the instructor keep in mind the following principles of learning.

- All individuals do not learn at the same rate.

- Success encourages and failure disheartens. Nothing succeeds like success.

- Learning means a change in behavior.

- One learns best when he is ready to learn.

- A person learns by doing. The more he is involved the more he is likely to learn. He learns when he solves problems, looks up facts, asks questions, compares ideas, operates machines, and uses equipment.

- One learns best when he feels secure.

- Experiences are more meaningful when built upon step-by-step learning situations.

1442

14446

KEY NUTRIENTS

Lesson 7: VITAMIN A

PURPOSE

Trainer agent to help aides:

1. Learn the importance of Vitamin A and how the body uses it.

2. Learn foods containing Vitamin A and how to include them in the diet.

PRESENTATION

. Present a brief overview of the functions and characteristics of vitamins. Emphasize these points:

- Vitamins are essential for body growth to resist infection, and to keep the body functioning properly.

- All vitamins needed for good health can be found in food.

- Vitamins may be classified as fat-soluble or water-soluble. Fat-soluble vitamins can be stored in the body. Water-soluble vitamins cannot be stored in the body to any significant extent. Therefore, foods containing water-soluble vitamins should be eaten every day.

. Point out the characteristics of Vitamin A. This vitamin is:

- Fat-soluble and can be stored in the body.

- Fairly stable to heat.

14447

- Discuss and show the specific functions of Vitamin A in the body. Refer to flip charts "How Food Affects You" pages 16-18 or slides 24 and 25 in slide set by same title, or to Key Nutrients leaflet.

- Emphasize that Vitamin A:

  - Helps the eyes adjust to dim light.

  - Helps keep the skin smooth.

  - Helps keep the lining of the mouth, nose, throat, and digestive track healthy and resistant to infection.

  - Promotes growth.

- Identify and discuss food sources of Vitamin A:

  - Animal sources are the only immediate sources of Vitamin A. Dark green, leafy, or deep yellow vegetables contain a substance called carotene, which is changed into Vitamin A by the body.

- Ask aides to identify animal sources of Vitamin A from the list of foods in Key Nutrients. Ask aides to explain why liver is high in Vitamin A.

- Display food sources of Vitamin A using pictures or food models such as:

  liver
  dark green leafy vegetables such as spinach
  broccoli, turnip greens, kale, collards
  deep yellow vegetables such as carrots,
  pumpkin, sweetpotatoes, winter squash
  apricots
  cantaloupe
  egg yolk
  butter and fortified margarine
  whole milk and cheese
  fortified milk and milk products

14449

- Compare the amounts of Vitamin A in light and dark green leafy vegetables; compare the amounts of Vitamin A in yellow and deep yellow vegetables. Show examples of these vegetables, such as lettuce and broccoli or corn and carrots.

- Indicate that dark green and deep yellow colors in vegetables usually indicate high Vitamin A value and that they add color and variety to meals.

- Point out that foods in the fruit and vegetable group are our main sources of Vitamin A. Illustrate with Daily Food Guide.

- Prepare two foods rich in Vitamin A such as a sweet-potato casserole or a salad made from greens.

- Have the aides select food recalls from several homemakers and evaluate the diets for Vitamin A content.

- Have the aides classify several recipes containing Vitamin A-rich foods into "good" and "fair" sources.

APPLICATION OF LESSON BY AIDES

Aides explain to homemakers the importance of Vitamin A in the body. Aides teach homemakers ways to include low-cost Vitamin A-rich foods in the diet.

REFERENCES FOR TRAINER AGENT

KEY NUTRIENTS

Lesson 8: B-VITAMINS

PURPOSE

Trainer agent to help aides:

1. Learn the function of three B-Vitamins: thiamine, riboflavin, and niacin.

2. Learn food sources of these B-Vitamins and ways of including them in the diet.

3. Understand the meaning of the terms "enriched" and "fortified" when used to describe food.

PRESENTATION

. Show pages 24-26 from flip charts "How Food Affects You." Point out that:

- Vitamin B, once believed to be a single nutrient, is now known to be composed of many vitamins. Thiamine, riboflavin, and niacin are three of these.

- B-Vitamins are water-soluble and therefore cannot be stored in the body. Foods containing these vitamins should be eaten every day.

. Discuss functions of B-Vitamins:

- Thiamine helps body cells obtain energy from food, helps keep nerves in healthy condition, and promotes good appetite and digestion.

14451

- Keep foods containing riboflavin away from the light. Do not leave milk on the doorstep in glass bottles or clear plastic containers.

- Use liquid from cooked meats and vegetables in soups, sauces, and gravies.

Have aides prepare a visual on enrichment that would be meaningful to a homemaker.

APPLICATION OF LESSON BY AIDES

Aides check local food stores for enriched and fortified products.

Aides help homemakers understand labels on enriched and fortified products.

REFERENCES FOR TRAINER AGENT

1. Food, Yearbook of Agriculture, 1959, USDA, pp. 139-149.

2. Eat to Live, Wheat Flour Institute, pp. 18-19, 30-33.

14453

14453

KEY NUTRIENTS

Lesson 9: VITAMIN C

PURPOSE

Trainer agent to help aides:

1. Learn how the body uses Vitamin C.

2. Learn food sources of Vitamin C and how to include Vitamin C food in the daily diet.

3. Learn how to help homemakers understand the importance of including Vitamin C in their diet each day.

PRESENTATION

- Have display of Vitamin C foods. Ask aides what nutrients are found in these foods.

- Mention that Vitamin C is also called ascorbic acid.

- Show slides 26 and 27 of the "How Food Affects You" slide set or pages 20-22 of the "How Food Affects You" flip charts to illustrate the following functions of Vitamin C in the body:

  - Helps hold body cells together and strengthens walls of blood vessels.

  - Helps in healing wounds.

  - Helps resist infection

- Have aides compare the ascorbic acid content of the following foods. Use Bulletin 72, Nutritive Value of Foods.

14454

brussel sprouts	oranges
collards	grapefruit
mustard greens	strawberries
green peppers	tomatoes
potatoes	cauliflower
turnip greens	cantaloupe
broccoli	cabbage

apples	pears
bananas	beets
watermelons	celery
peaches	corn

- Have aides group foods from both lists above into columns under these headings--best, good, and poor sources. This could be a reference for the aide to use with homemakers.

- Discuss precautions against loss of Vitamin C in cooking and storing.

- Use display of food to help aides determine low-cost sources of Vitamin C foods. Consider other foods: fruit drinks to which Vitamin C has been added, and fruits and vegetables in season.

- Have aides tell of other foods with which they are familiar that may be sources of Vitamin C.

- Have aides role-play ways of convincing homemakers to use low-cost Vitamin C foods.

14454

14455

Appendix

APPENDIX A

SAMPLE PERFORMANCE PRETEST

This performance test consists of two parts. Part A involves pattern placement, cutting, and marking and should help the instructor to evaluate the applicant's understanding of commercial patterns, manual dexterity in using some cutting and marking equipment, and ability to follow directions accurately. Part B relates to construction procedures and should give the instructor some understanding of the quality of the applicant's workmanship and comprehension of construction terms. The instructor may wish to change the pretest and use full-scale pattern pieces and additional fabric.

Before administering the pretest be sure that applicant understands:

- What he is expected to do
- Time limits for the test
- Procedures to be used in evaluating and reporting test results

PART A - PATTERN PLACEMENT, CUTTING, AND MARKING

Materials required:

- Piece of fabric measuring 12 by 36 inches
- Set of pattern pieces - (examples on following pages)
- Sewing equipment
- Test instructions

Directions: Perform the following steps using the materials provided.

(1) Prepare the fabric so that it measure 12 by 36 inches. Fold it so there is a 12- by 12-inch square of single thickness and a 12- by 12-inch square of double thickness as shown in the drawing.

(2) Lay patterns A, B, C, and D on the section of double thickness as indicated on the drawing. Do not cut out patterns at this step.

(3) Place patterns E and F on the section of single thickness.

SDAI 1443

APPLICATION OF LESSON BY AIDES

Aides help homemakers understand the importance of Vitamin C in the diet.

Aides select dietary recalls from several homemakers and evaluate for Vitamin C.

Aides plan with homemakers ways to include low-cost Vitamin C foods in families' diets.

REFERENCES FOR TRAINER AGENT

1. Food, Yearbook of Agriculture, 1959, USDA, pp. 150-161.

5. Family Fare, G1, USDA, p. 12.

14456

KEY NUTRIENTS

Lesson 10: VITAMIN D

PURPOSE

Trainer agent to help aides:

1. Learn the functions of Vitamin D in the body.

2. Learn sources of Vitamin D and how to obtain the recommended amounts.

PRESENTATION

. Refer to the leaflet Key Nutrients and discuss functions of Vitamin D in the body. Point out that:

- The first formation of bone is known as cartilage.

- Calcium and phosphorus are the minerals that cause the cartilage to harden into bone.

- When Vitamin D is not present in the diet, cartilage does not harden completely, resulting in soft curved bones, bowed legs, or knock knees. This disease is known as rickets.

. Show a picture of a child with rickets and point out deformities of bone structure.

. Show slides 30 and 31 from "How Food Affects You" slide set. Emphasize:

- Infants and children need Vitamin D for growth.

- Adults need small amounts of Vitamin D to keep bones and teeth healthy.

- Pregnant and lactating women need additional amounts to ensure healthy babies and to protect their own bodies.

14456

 14457

- Point out food sources of Vitamin D:

  - Salt water fish, herring, mackerel, and canned salmon and sardines are sources. Egg yolk and liver contain Vitamin D in varying amounts.

  - Milk is generally not a good source unless it is fortified with Vitamin D. Read labels for Vitamin D content.

  - Cod-liver oil and halibut-liver oil are excellent sources of both Vitamin A and Vitamin D.

  - Human skin contains a fat which is transferred into Vitamin D when it is exposed to the ultraviolet rays of direct sunlight. Clouds, fog, dust and clothes interfere with the absorption of these ultraviolet rays.

- Discuss amounts of Vitamin D needed. Vitamin D is required throughout the growth period. The amount recommended is 400 USP units per day from infancy through age 22. The requirement for pregnant and lactating women is the same as for growing children. Enough Vitamin D can generally be obtained by drinking amounts of milk recommended in the Daily Food Guide.

  - Since Vitamin D is fat-soluble and is stored in the body, excessive amounts can be harmful. Toxic effects, including loss of appetite, vomiting, diarrhea and drowsiness, appear in children consuming massive amounts. Toxic effects do not result from Vitamin D in foods.

  - Concentrated forms of all vitamins should be prescribed by a physician.

14429

14458

APPLICATION OF LESSON BY AIDES

Aides check with young mothers to see if children are drinking Vitamin D milk and are being exposed to sunshine.

Aides visit local markets to determine availability of Vitamin D milk and report findings at later training meetings.

ABSTRACT - This booklet is one of a series of booklets of supplemental lessons in food and nutrition prepared by the Extension Service of the U.S. Department of Agriculture and is designed for use by trainer agents in on-the-job training of Extension aides to provide them with information about meal planning and with teaching methods to use in helping families. Purposes, presentation suggestions, learning activities, references, and audiovisual materials accompany these units: (1) Low-Cost Meals, (2) Planning for Snacks, (3) Planning for a Good Breakfast, (4) Quick and Easy Meals, (5) One-Burner Meals, (6) Casserole Meals Without a Recipe, (7) Meals for One or Two, and (8) Meal Planning to Include an Older Person, During Pregnancy, and When There Is a Weight Problem. Additional suggestions for the trainer agent and lists of recommended references are provided in an introductory section. Related booklets are available as VT 012 840-VT 012 843, all in this issue. LESSONS - MEAL PLANNING

Lesson 1: Low-Cost Meals 8
Lesson 2: Planning For Snacks 13
Lesson 3: Planning for a Good Breakfast 16
Lesson 4: Quick and Easy Meals 20
Lesson 5: One-Burner Meals 23
Lesson 6: Casserole Meals Without A Recipe 26
Lesson 7: Meals for One or Two 29
Lesson 8: Meal Planning to Include An Older Person 32
Lesson 9: Meal Planning During Pregnancy 35
Lesson 10: Meal Planning When There is a Weight Problem 38

Meal Planning is one of a series of booklets of supplemental lessons in food and nutrition, designed for use in on-the-job training of Extension aides. These lessons are not intended to be complete teaching units. The purpose is to enrich the aides' background in food and nutrition and to provide practical teaching methods that they can use in taking food and nutrition information to families. Since technical subjects in nutrition are simplified some of the generalizations may have exceptions.

14463

FOOD AND NUTRITION

Supplemental Lessons for Training Extension Aides

MEAL PLANNING

Purpose

These lessons were written to help trainer agents prepare aides for work with families in the Food and Nutrition Education Program. It is important that aides understand the principles of planning meals to include nutrition, family needs and preferences as well as cost.

The lessons are on expansion of Lesson 8 - Plan Meals to Meet Family Food Needs from Food and Nutrition---basic lessons for training Extension aides. The information can be adapted by the aides for the families they work with. It also can be used in teaching groups of adults or youth. This series should be used to supplement the initial training given aides and will help the trainer agent enlarge the food and nutrition knowledge of the aides.

TRAINER AGENT'S RESPONSIBILITY

References are suggested for the agent's use with each lesson. The agent will find it helpful to assemble these references before starting the lessons and to use them in her preparation for teaching.

References also are suggested for the aide's use. The agent should be selective in the references she gives to aides. Order those selected well in advance.

Go over references thoroughly with the aides so that they know what is in each reference.

Professional people in related fields may be asked to participate in training meetings. Such participation should be planned well in advance.

14465 14464

A working relationship with each aide should already be established as a result of the initial training period. Effective communication remains vital in teaching. Before teaching supplemental lessons, the trainer agent may wish to review purposes of the training and the importance of aides' participation.

Suggested check list to be sure that all necessary preparations for the in-service training sessions have been made:

___Meeting place with necessary facilities has been obtained.

___All references needed to complete the lessons have been assembled.

___Local public health service and library have been checked for additional references.

___All visual materials and equipment needed to teach the lessons are on hand.

___All reference materials needed for the aides have been obtained.

___All lesson plans have been carefully studied so that you fully understand the overall content of the course.

___Sufficient time has been allowed to complete each lesson.

ADAPTING THE LESSONS TO YOUR AIDES

Guides used in teaching the basic lessons should be followed in teaching the supplemental lessons also:

Adapt training classes to meet the needs of your group. Here are some ideas to keep in mind:

1. Simplify. Do not try to cover too much material in one lesson. Pick out the most important points and emphasize them.

2. Use colorful visuals and a dynamic presentation to help make the lesson more appealing.

3. Emphasize good nutrition elements in the food the aides are now eating. Point out how small changes can often result in a more balanced diet.

14465

(4) Ask the instructor to check pattern layout. The instructor will tell you when you may cut out the pieces. Keep remaining fabric for use in Part B.

(5) After pieces are cut out, mark darts and sleeve markings with tracing paper and wheel. Mark center front line, fold line, and buttonholes with basting thread.

PART B - CONSTRUCTION PROCEDURES

Directions: Perform the following steps using the materials from Part A.

(1) Use the bodice front and back to illustrate the following:
Directional staystitching
Correctly sewn darts
Seam construction on shoulder using a $\frac{1}{4}$-inch seam

(2) Use the facing pieces, bodice, and sleeve to show how to:
Join neck facings
Finish outer edge of facings
Apply facings to neck edge and one armhole
Apply sleeve to the other armhole

(3) Put in two rows of machine stitches for gathering across one side of the 6-inch square. Use a $\frac{5}{8}$-inch seam allowance and put a lower row of stitching in the seam line. Do not pull the gathers.

(4) Hem the opposite side of the 6-inch square as in a gathered cotton skirt without seam binding. Turn under $\frac{1}{4}$ inch from the edge. Make a $1\frac{1}{4}$-inch hem. Sew hem by hand using a slip stitch or blind stitch.

(5) Construct the collar correctly. Do not put on bodice.

(6) Label the bodice, fabric square, and collar with your name and present to the instructor.

4. Involve the aides in the training meetings in as many ways as possible.

EXTENDING INFORMATION

Information given in the supplemental lessons may be effectively used in other ways, such as adaptation for use in training volunteer leaders or in newsletters or newspaper articles. A series of radio or TV programs based on the lessons may help to extend to a larger audience the ideas that aides are promoting.

14466

Recommended publications

For aides and leaders

Publications and visual materials are listed with each lesson. Make sure that supplies of them are on hand before you begin teaching.

USDA

Bulk quantities of USDA pamphlets are usually obtained through your State publications distribution officer.

Calories and Weight, G-153 (25¢)
Eat A Good Breakfast to Start A Good Day, L268 (5¢)
Family Fare, G-1 (45¢)
*Food and Your Weight, G-74 (15¢)
Food Guide for Older Folks, G-17 (10¢)
*Meal Planning Made Easy, PA-695 (5¢)
Money Saving Main Dishes, G-43 (30¢)
*Daily Food Guide Leaflet, C&MS-23 (35¢ for 10 copies)
Free illustrated Daily Food Guides are available for educational programs relating to U.S. Department of Agriculture's Family Food Assistance Programs through your regional Food & Nutrition Service office.

Cereal Institute, Inc.

Breakfast Source Book, pp. 7-14, Cereal Institute, Inc. 135 South LaSalle Street, Chicago, Ill. 60603.

*Publications NOT available free may be purchased from Superintendent of Documents, Government Printing Office, Washington, D.C. 20402, at the prices indicated. There is a 25 percent discount for 100 or more copies on all GPO orders.

14467

Florida Citrus Commission

Teen Temptations, Florida Citrus Commission, Institutional and School Marketing Dept., P.O. Box 148, Lakeland, Florida 33802.

Kellogg Company

Why Break the Fast?, Resource Kit, Kellogg Company, Battle Creek, Michigan 49016.

National Dairy Council

An Album of Snacktime Hits, B16 (3¢)

14470

MEAL PLANNING

Lesson 1: LOW-COST MEALS

PURPOSE

Trainer agent to help aides:

1. Identify low-cost food sources in the Daily Food Guide and ways they can be included in food plans for the day.

2. Develop skill in planning nutritious low-cost meals and snacks.

3. Learn ways to help homemakers include low-cost foods to improve the nutrition of the family.

PRESENTATION

. Ask aides to name low-cost foods under each of the four food groups which could be used in meals and snacks. List on chalk board.

- Milk Group

-- Nonfat dry milk and evaporated milk are cheaper than fresh milk.

-- Cream is expensive. Whipped evaporated or whipped nonfat dry milk usually can be used in place of whipped cream. They have more calcium and protein, less fat, and fewer calories than cream.

-- Less expensive cheese products such as processed cheese and cheese food are a good source of protein and calcium. More expensive cheeses may not provide more nutrients.

14471

14470

- Meat Group

  -- Dried beans, peas, and peanut butter make hearty dishes. Use in combination with an animal protein to improve the quality of the vegetable protein.

  -- Eggs are usually a less expensive source of protein than most meats.

  -- The nutritive value of ground beef, liver, heart, and kidney is good for the money spent.

  -- Chicken and turkey are good buys when they are plentiful.

  -- Locally caught fresh fish, canned fish flakes (such as mackerel) and frozen fillets are usually good buys.

  -- Meat in combination with a white sauce or with macaroni, spaghetti, noodles or rice can reduce cost and extend the nutritive value of the pasta.

- Fruit-Vegetable Group

  -- Fresh vegetables that are in season and plentiful are better buys than those purchased at other times.

  -- Frozen spinach and other greens, chopped broccoli, squash, peas, and green beans may be good buys, as compared with the fresh vegetable.

  -- Cabbage, potatoes, and root vegetables such as carrots are usually good vegetable buys.

  -- Canned tomatoes are cheaper and often higher in vitamin C than raw tomatoes out of season.

  -- Canned greens, pumpkin, and green beans are usually economical buys.

  -- Canned vegetables usually cost less than frozen.

  -- During most seasons, frozen orange juice is cheaper and has about the same nutritive value as fresh.

14472

- Breads and Cereals

  -- Plain bread or rolls are lower in cost than sweet or fancy-shaped rolls.

  -- Enriched and whole grain breads and cereals supply more nutrients for the money than unenriched products.

  -- Day-old bread, which can be purchased at food stores or special outlets, costs less.

  -- Homemade bread and cookies are usually lower in cost than similar purchased items.

. Use Comparison Cards to compare nutritive values of low-cost foods with more expensive foods in the same food group.

. Plan a day's meals and snacks around some of the low-cost foods which have been listed. Use the Daily Food Guide in planning. Use pictures or food models to illustrate.

. Other points to consider when planning low-cost meals and snacks:

  - Use resources which are available.

    -- Food supply on hand.

    -- Leftovers.

    -- Food from the garden.

    -- USDA donated foods or food stamps, whichever is available.

    -- Specials at the grocery store -- some advertised foods may not be "specials."

  - Plan simple meals.

  - Use recipes that can be prepared without costly ingredients.

  - Make a shopping list.

14473

- Show filmstrip or slide set "The 'Basic Four' Way to Good Meals." Analyze meals for good nutrition and cost. Discuss ways in which meal costs could be lowered but still be nutritious. What adjustments could be made? Discuss with aides.

- Aides plan a day's meals and snacks around USDA donated foods if available to families. Include low-cost food items which need to be purchased, or:

- Aides plan a day's meals and snacks around "specials" which are currently being advertised in the local papers. Use the Daily Food Guide in planning.

- Make plans to prepare and serve one of the low-cost meals at a later training session.

APPLICATION OF LESSON BY AIDES

Aides apply lesson to their own family meal planning.

Aides apply information as they work with individual homemakers.

Aides use information when teaching small groups.

MEAL PLANNING

Lesson 2: PLANNING FOR SNACKS

PURPOSE

Trainer agent to help aides:

1. Understand how snacks help meet daily food needs.
2. Learn ways to help homemakers include nutritious, low-cost snacks in a daily food plan.

PRESENTATION

- Display some typical snack foods such as soft drinks, ice cream, candy, cake, cookies, potato chips, fruits, etc. Ask aides to group the foods according to the four food groups. Some will not fit into the four food groups. Discuss the food value and relative cost of the snacks using the comparison cards.

- Aides indicate the number of times they have eaten within the last 24 hours. Emphasize that snacks may provide a large portion of the day's food for many people.

  - What foods do aides and their own families eat between meals? List these foods in columns with the following headings: milk, meat and substitutes, fruits and vegetables, breads and cereals, and other foods.

  - Compare the nutritive value of these foods. Do most of these snacks fit into the four food groups or are they other foods?

  - What are advantages of selecting snacks from the four food groups?

- Are snacks good for us? Yes and no. It depends upon:

  - the time the snack is eaten. Sweet, rich foods eaten shortly before meal time dull the appetite for the next meal.

14476

- the amount of food eaten. Too much food eaten between meals may lessen the appetite for foods at meal time.

- kinds of food selected. Foods which contain little food value other than calories are generally poor choices. These are called empty calorie foods. Examples are soft drinks, candy and potato chips.

- relationship of the snack to the other foods eaten during the day. Snacks should help meet the food needs as recommended in the Daily Food Guide.

- the person who eats the snack. Many people may not get all of the food needs at mealtime so snacks can help meet these needs. Examples are: growing children, active teenagers, adults who do heavy work, and those who need to gain weight.

  -- It may be more satisfying for overweight people, who are losing weight, to eat smaller amounts of food but more frequently.

. Put guidelines for choosing snacks on chalkboard or newsprint.

  - Choose snacks from the four food groups in the Daily Food Guide.

  - Avoid empty-calorie foods. They are expensive for the nutrients supplied.

  - Select according to the needs of the individual.

  - Select good snack choices such as fresh fruit, vegetable nibblers, milk, fruit juice, plain cookie, and small open-faced sandwich.

. Aides divide into groups. Each group plan a day's meals with a morning and an afternoon snack. Ask them to use the USDA donated foods currently being offered in the community or low-cost foods. Examples of low-cost snack items might be cocoa made from nonfat dry milk, carrot nibblers, cornmeal, oatmeal, or peanut butter cookies.

14477

- Use low-cost nutritious snacks at training session. If time permits, have aides prepare one low-cost nutritious snack which they planned.

APPLICATION OF LESSON BY AIDES

Aides use information to help homemakers plan snacks which supplement their meals.

Aides use information in teaching small groups.

REFERENCES FOR TRAINER AGENT

1. Consumers All, Yearbook of Agriculture, 1965, pp. 393-397.

14479

14480

MEAL PLANNING

Lesson 3: PLANNING FOR A GOOD BREAKFAST

PURPOSE

Trainer agent to help aides:

1. Know the advantages of eating breakfast.

2. Learn the characteristics of a good breakfast.

3. Learn ways to help homemakers plan nutritious breakfasts to meet individual needs.

PRESENTATION

. Use poster What Did You Have For Breakfast This Morning? to open discussion about breakfast.

. Conduct a poll among aides regarding the following questions. Use responses as a basis for discussion.

- What does the word "breakfast" mean to you?

- Did you eat breakfast this morning?

- Did everyone in your family eat breakfast?

- What foods do you like for breakfast? As foods are mentioned, separate into the four food groups and other foods.

. Discuss why breakfast is important

- Show slides, "Breakfast and the Bright Life" or filmstrip "Why Eat A Good Breakfast." Review breakfast study reported in Breakfast Source Book.

- Studies show that a midmorning coffee break does not replace breakfast.

14480

- Body uses nutrients more efficiently when they are distributed throughout the day.

. Discuss why people skip or skimp breakfast. Aides role play or respond to these statements and suggest ways to cope with problems.

  - I don't eat breakfast. I'm on a diet.

  - I don't like eggs, bacon and cereal that are usually eaten at breakfast.

  - I'm just not hungry enough to eat breakfast right after I get up. I'd rather have a cup of coffee in the middle of the morning.

  - We don't have enough money to have food in the morning.

  - I'm too rushed in the morning. I'd rather sleep late and skip breakfast.

  - If anyone in our house eats breakfast, he just grabs something from the refrigerator.

  - I'm too busy fixing my hair and putting on makeup to bother with eating.

. Use Comparison Cards and food models or actual foods. e.g. Compare nutritive value and calories in a breakfast with empty-calorie snacks and heavy desserts.

. Review guidelines in Eat a Good Breakfast to Start a Good Day. A good breakfast:

  - gives protein, minerals, and vitamins.

  - provides fuel for energy.

  - tastes good.

. Show pictures of traditional and non-traditional breakfasts which meet the guidelines for a good breakfast.

14481

- Have aides plan a low-cost nutritious breakfast around these situations:

  - prepared without cooking.
  - without foods from the meat group.
  - featuring USDA donated foods if available.
  - low in calories.
  - featuring foods used by a local cultural group.

APPLICATION OF LESSON BY AIDES

Aides stress, with program families and groups, the importance of breakfast.

Help change attitudes and behavior regarding breakfast.

REFERENCES FOR TRAINER AGENT

1. Food For Us All. Yearbook of Agriculture, 1969, p.320.

REFERENCES FOR AIDES

Eat a Good Breakfast to Start a Good Day, Leaflet 268, USDA.

Food, A Key to Better Health, Nutrition Foundation, p. 6.

EVALUATION

Several weeks after the lesson, ask aides to evaluate breakfasts which were eaten by the families they visited on one day. Also check number of aides now eating breakfast and compare with the poll.

14483

MEAL PLANNING

Lesson 4: QUICK AND EASY MEALS

PURPOSE

Trainer agent to help aides:

1. Learn ways to plan nutritious meals that can be prepared with a minimum of time, energy and skill.
2. Plan a day's food that a person with limited abilities could prepare.

PRESENTATION

- Review lesson 8 from Food and Nutrition...basic lessons for training extension aides and discuss the quality of the meals in terms of nutrition, color, texture, flavor and cost. Make up your own or use these menus:

- Write two menus on the board.

Menu 1	Menu 2
Scrambled Eggs	Poached Eggs
Buttered Canned Green Beans	Frozen Green Beans with Bacon
Sliced Tomatoes	Tossed Salad
Bread and Spread	Toast and Spread
Peanut Butter Cookies	Peanut Butter Cookies
Milk	Coffee

- Aides identify the menu which would be easiest to prepare and give reasons for their choice.

- Aides make suggestions for planning simple nutritious meals children could prepare for the family.

- Food preparation can be simplified by planning meals that:

  - limit the number of foods served.

- include foods which require little attention during preparation.

- require the simplest methods of food preparation.

- can be prepared from low-cost convenience foods which are partially or completely prepared.

    -- Canned foods and mixes simplify food preparation.

    -- Homemade biscuit, cookie, cocoa and pudding mixes are economical and simplify meal preparation.

- use foods prepared in advance.

    -- Fresh fruits and vegetables can be cleaned and refrigerated for later use.

    -- Eggs can be hard cooked and refrigerated for later use.

. Show slides or filmstrip "The 'Basic Four' Way to Good Meals."

    - Analyze the meals for nutrition, eye appeal and ease of preparation.

    - How can the menus be adjusted so that the meals could be simpler to prepare?

. Aides plan a quick breakfast, a carried lunch or a simple supper using the Daily Food Guide and the time-saving suggestions which have been discussed.

APPLICATION OF LESSON BY AIDES

Aides "child-test" the meals they planned for ease and simplicity in food preparation.

Aides use information with individual families and small groups.

14485

1447 1446

MEAL PLANNING

LESSON 5: ONE-BURNER MEALS

PURPOSE

Trainer agent to help aides:

1. Assist homemakers to plan nutritious meals when cooking facilities are limited.

PRESENTATION

. Aides tell of situations they have known when cooking facilities were very limited.

- Limitations might include:

-- no oven

-- no refrigerator

-- poor storage space for staples

-- limited cooking equipment

- Examples of program families in which cooking facilities may be limited:

-- older people on limited incomes.

-- families living in poor housing.

-- families whose homes have been destroyed through disasters such as storms, floods, and fires.

. Discuss how to plan meals where cooking facilities are limited.

- Consider the situation:

-- Heat source. If there's only one gas or electric unit, plan for one dish meals, double-decker cooking using a double boiler and keeping food hot while another cooks.

14488

14487

-- Refrigeration space. If there's no way to keep perishables cold, use canned foods and dry storage items such as dry milk and mixes. Plan amount of food needed so there will be no perishable leftovers.

-- Storage space for non-perishable foods. If storage is poor, use cans and jars with tight-fitting lids.

- Meal plan

-- Use simple menus. Limit number of foods served.

-- Use the Daily Food Guide in planning meals and snacks.

-- Plan to use some foods which require no cooking.

- Illustrate planning food for a day when there are limited cooking facilities. Write on board, illustrate with food models or pictures on a poster.

. Use the following example: Family - an elderly couple living in one room.

- Cooking facilities - hot plate, heavy skillet with lid, double boiler, mixing bowl, can opener, knife, cup, spoon, and limited refrigerator space.

- Meal Plan for A Day

Breakfast	Lunch
Tomato Juice	Beef Stew
Oatmeal with Milk	Hot Corn Bread with Spread
Milk	Cabbage Slaw
	Milk

Supper

Canned Chopped Meat and Potato Casserole
Corn Bread and Spread
Spinach
Carrot Strips
Custard
Coffee

14488

14487

- Evaluate the meals using the Daily Food Guide.

- Ask aides to plan order of preparation of these foods and the equipment to be used.

APPLICATION OF LESSON BY AIDES

Aides plan low-cost food for a day using the following situation. Plan meals for a young family - mother, father, and two pre-school children. They have these things for cooking and storing food: Electric skillet, hot plate, saucepan, can opener, knife, spoon, fork, and containers with lids for storing staples.

Aides prepare one of these meals using the limited facilities described.

Aides use this experience as background information as they work with individual families or small groups.

REFERENCES FOR TRAINER AGENT

1. Recipe booklets which are developed by electric skillet manufacturers.

VISUALS AND EQUIPMENT

Chalkboard or newsprint.

Pictures of food or food models.

Daily Food Guide, poster, F&NS-13, USDA.

REFERENCES FOR AIDES

1. Daily Food Guide, leaflet, C&MS-23, USDA.
2. Meal Planning Made Easy, PA-695, ES-USDA.
3. Family Fare: Food Management and Recipes, G-1, USDA.
4. Food Guide for Older Folks, G-17, USDA.
5. Money Saving Main Dishes, G-43, USDA.

14489

MEAL PLANNING

Lesson 6: CASSEROLE MEALS WITHOUT A RECIPE

PURPOSE

Trainer agent to help aides:

1. Recognize advantages of using low-cost main dish casseroles in meals.

2. Learn the basic components of a main dish casserole.

PRESENTATION

- Discuss advantages of planning for main dish casseroles.

  - preparation can often be done in advance.

  - provides a way to use leftovers.

  - provides a way to extend meat.

  - provides a main dish to please the family.

  - enables homemaker to be creative.

- Write a main dish casserole recipe on the board. Indicate the food group to which each component belongs.

  - A main dish casserole may be made without a recipe using these suggestions:

    1 part protein food such as meat, fish, egg or cheese
    2 parts cooked starchy food such as noodles, rice or macaroni
    2 parts vegetables such as beans, peas, tomatoes, carrots, asparagus or celery
    sauce enough to moisten, such as gravy, white sauce, or canned cream soups
    a crunchy topping such as bread or cracker crumb seasoning
    bake at moderate temperature (350F)

14489

14490

- Demonstrate the preparation of a casserole. One combination might be:

  1 cup cooked chopped beef
  2 cups cooked rice
  2 cups cooked green beans
  1 can condensed tomato soup
  1 chopped onion
  buttered bread crumbs

  This amount will make six servings.

- While demonstrating, give information concerning nutrition and meal planning.

  - Animal protein (beef) and cereal protein (rice) are combined in this casserole. Cereal protein is not as good quality as animal protein. When combined with animal protein, its quality is improved.

  - The amount of green beans in a serving of this casserole is not considered a serving of vegetables in the Daily Food Guide (1/2 cup is a serving).

  - Some ingredients in casserole recipes such as mushrooms, pimiento and olives usually increase cost but may make it more appealing.

- Give information concerning meal planning.

  - Suggest foods which can be added to complete this meal such as a carrot-raisin salad, cornbread, and milk.

  - Have aides help plan the remaining food for the day. Use Daily Food Guide.

- Aides make lists of low-cost protein foods, starchy foods, vegetables, sauces, and seasonings which might be used in preparing casseroles.

14491

APPLICATION OF LESSON BY AIDES

Aides apply information to their own meal planning by preparing and taste-testing a main dish casserole. Tell what other foods they served with the casserole.

Aides use information with individual families and small group meetings.

REFERENCES FOR TRAINER AGENT

1. Selected recipe books on casseroles or one-dish meals.

VISUALS AND EQUIPMENT

Chalkboard or newsprint.

Demonstration supplies and equipment.

Daily Food Guide, poster, F&NS-13, USDA.

4. Money-Saving Main Dishes, G-43, USDA.

MEAL PLANNING

Lesson 7: MEALS FOR ONE OR TWO

PURPOSE

Trainer agent to help aides:

1. Expand their knowledge related to planning meals for one or two.

2. Learn ways to help homemakers plan meals.

PRESENTATION

- Have aides tell group about persons with whom they are working who live alone or with another person. Keep a running record of:

  - approximate ages.

  - type of kitchen facilities they have.

  - types of food and nutrition problems already identified.

  - kinds of foods they most often fix for themselves.

  - evident health problems.

- Point out advantages of planning, preparing and serving meals for one or two people.

  - Fewer individual needs and preferences to consider.

  - Less work and time in preparation.

  - Can eat what and when they wish.

14493

- Discuss disadvantages when planning, preparing and serving meals for one or two. Consider ways to overcome their problems.

  - Lack of variety in foods may result in poor nutrition. To get more variety,

    -- Buy in small quantities.

    -- Include convenience foods in meal plan. Example: Frozen dinners served with other foods can make a nutritious meal.

    -- Use USDA food stamps or donated foods if available.

  - Lack of appetite may result in poor nutrition.

    -- Boredom contributes to poor appetite.

    -- Have meals with friends occasionally.

    -- Plan meals for eye and taste appeal. Include a variety of colors, flavors and textures in a meal.

    -- Vary place where meals are eaten. Eat in front of a window, on a balcony.

    -- Take walks to stimulate appetite.

  - Preparation of too much food may result in waste. To avoid waste:

    -- Use leftovers in a variety of ways.

    -- Exchange foods with friends occasionally.

- Display food in various can and box sizes and compare costs.

- Review bulletin, Food Guide for Older Folks.

- Use Daily Food Guide as an aid in planning. It gives the number of servings per day by age groups.

14494

APPLICATION OF LESSON BY AIDES

1. Aides make visuals of colorful and colorless meals.

2. Each aide plan low-cost meals for two days for one or two people. Show how food planned for first day can be used in meals or snacks for the second day.

3. Aides apply information to families of one or two with whom they work. Help families find solutions to problems.

Lesson 8: MEAL PLANNING TO INCLUDE AN OLDER PERSON

PURPOSE

Trainer agent to help aides:

1. Learn how the family's daily food plan can be adjusted to meet the needs of older folks.

2. Learn ways to help homemakers adjust family meals.

PRESENTATION

- Review lessons 6 "Food Needs Throughout Life" and 8 "Plan Meals to Meet Family Food Needs" in Food and Nutrition...basic lessons for training extension aides. Emphasize that older persons need:

  - fewer calories because of reduced activity.

  - the same nutrients as other family members, but in different amounts, and

  - amounts and kinds of food in the Daily Food Guide to supply the nutrients needed.

- Adjust family meals to meet the special needs of an older person. Discuss why changes are needed and how to make them.

  - Processes of digestion slow down, therefore--

    -- Use fewer rich fatty foods like pastry, whipped cream, fat meats, and gravies.

    -- Serve frequent small meals rather than large meals less often.

14496

PATTERN PIECES FOR PRETEST

Back Facing

Armhole Facing

- Teeth are often missing or dentures poorly fitted so plan for foods which can be easily eaten.

    -- ground meats or chopped meats.

    -- soft foods.

    -- beverages which contain more than, calories.

    -- cream soups.

    -- chopped raw vegetables.

- Food likes and dislikes are well established.

    -- Know food likes and dislikes.

    -- Include well-liked nutritious foods often.

- Health problems may necessitate changes in diet. Follow instructions from physician.

- Older people need fewer calories. Avoid empty-calorie foods. Plan for smaller servings.

. Plan a suitable routine.

    - Have regular meals.

    - Serve an easily digetsed meal at night.

    - Plan from the Daily Food Guide.

    - Reserve part of the family meal for a mid-morning or mid-afternoon snack.

    - Include milk in meals and snacks.

. Have aides describe a program family in which there is an older person. Plan a day's meals and snacks for the family.

14497

APPLICATION OF LESSON BY AIDES

Aides make a list of appropriate in-between meal snacks for older people.

Aides apply information as they work with families including older people.

REFERENCES FOR TRAINER AGENT

4. Food Guide for Older Folks, G-17, USDA.

EVALUATION

Make home visits and have conferences with aides to see how they use information with families including older people.

14498

14497

MEAL PLANNING

Lesson 9: MEAL PLANNING DURING PREGNANCY

PURPOSE

Trainer agent to help aides:

1. Understand the increased nutritional needs during pregnancy.

2. Learn how the family's food plan can be adjusted to meet the needs of the pregnant woman.

PRESENTATION

- Review Lesson 6, "Food Needs Throughout Life" in Food and Nutrition...basic lessons for training extension aides.

- Discuss section on food for pregnant women in Food, A Key to Better Health, pp. 14 and 15.

- List adjustments to be made in the food intake by the pregnant woman.

  - Increase intake to three cups of vitamin D milk.

  - Use more foods in the four food groups and less from the additional foods in meals and snacks.

  - Stress the importance of a balanced diet during pregnancy.

- Review the value of vitamin D fortified milk.

- Discuss ways the pregnant woman may get more milk into her diet as she plans family meals and snacks. List on board as aides contribute answers or illustrate with pictures or food models.

14300

14499

- Use milk as mid-morning and mid-afternoon snack.

- Include more cheese in meals.

- Plan for more milk desserts -- ice cream, puddings, custards.

- Plan to use cottage cheese in main dish or in salads.

- Plan meals around soups made with milk. Suggest use of vitamin D fortified evaporated milk, dry skim and whole milk.

. Show and discuss one of the following slide sets or filmstrips: "Food Value Stretchers," "Milk the Magnificent," "The 'Basic Four' Way to Good Meals" or "Milk, Basic to Good Nutrition."

APPLICATION OF LESSON BY AIDES

Aides plan meals and snacks for the day for a program family including a pregnant woman. Evaluate the meals using the Daily Food Guide. Also, consider variety in flavor, color and texture. Calculate the amount of milk in the meals and snacks in this assignment to see if they include more for the pregnant woman.

Use as background to help pregnant homemakers plan meals.

14501

MEAL PLANNING

Lesson 10: MEAL PLANNING WHEN THERE IS A WEIGHT PROBLEM

PURPOSE

Trainer agent to help aides:

1. Learn to adjust the family's food plan to meet the needs of a member who has a weight problem.

PRESENTATION

- Review pages 16-19 in Food, A Key to Better Health.
  - Emphasize the chief reason for overweight is an imbalance of calories and activity.
  - Illustrate this balance with pictures or a poster.
  - Show selected slides from "The Oopsies."
  - Stress the need for encouragement by family members for the person trying to lose weight.
- Plan family meals so that the calorie counter can enjoy them, too.
  - Build meals around familiar well-liked foods. Crash diets will not change food habits. They are often monotonous and short-lived and ineffective.
  - Plan adequate meals and snacks with emphasis on the four food groups.
  - Show that the minimum number of servings recommended by the Daily Food Guide will supply approximately 1200 calories which, for most women, would be a safe reducing diet. Include kinds and amounts of food which will yield fewer calories. Draw these from the aides and list on the board:

14502

-- Trim fat from meat before cooking.

-- Keep servings small for the "calorie counter."

-- Serve sauces, gravies and dressings separately so they may be avoided.

-- Add butter to vegetables at the table.

-- Use skim milk rather than whole milk in cooking and drinking.

-- Use fruit, (fresh or cooked with little sugar) rather than pastries, cakes and cookies.

-- Plan to use more low-starch vegetables.

-- Prepare meat without added fat.

-- Bake, boil or broil rather than fry foods.

- Have aides identify starchy and non-starchy vegetables using pictures or food models.

- Show how a family's food plan can be adjusted to meet the needs of a person who is trying to lose or gain weight. Use suggested menus in Food and Your Weight as a guide.

APPLICATION OF LESSON BY AIDES

Aides use information as they work with program families who have a weight problem.

REFERENCES FOR TRAINER AGENT

1. Food For Us All, Yearbook of Agriculture, 1969, pp. 304-314.

ABSTRACT - Prepared by the Extension Service of the U.S. Department of Agriculture, this teaching guide is for trainee agents use in on-the-job training of Extension Aides and is designed to provide aides with the information they need to help families improve their diets. The information, which is to be provided during the initial three weeks training and later during weekly meetings, is organized in these lessons: (1) Food Makes the Difference, (2) Daily Food Guide, (3) Key Nutrients, (4) Foods Contain Different Amounts of Nutrients, (5) How Your Body Uses Food, (6) Food Needs Throughout Life, (7) Feeding Young Children, (8) Plan Meals to Meet Family Food Needs, (9) Get More for the Food Dollar, (10) Comparative Food Shopping, (11) Preparation of Milk, Milk Products, Vegetable, Fruit, Meats, Breads, and Cereals, and (12) How to Make a 24-Hour Dietary Recall. Purposes, presentation suggestions, learning activities, references, evaluation methods, supplemental lesson suggestions, audiovisual materials, and equipment accompany each lesson. An introductory section provides additional suggestions for the trainer agent and lists recommended references. Related booklets are available as VT 012 840-VT 012 842, all in this issue. (SB)

FOOD AND NUTRITION...
basic lessons for training extension aides

Purpose of the lessons

These lessons were designed to help the trainer agent give aides the background in food and nutrition they will need for their work with low-income families.

In Extension's Food and Nutrition Education Program, trainer agents provide this background information to aides as part of the initial three weeks' training. After the aides start working with families, agents need to provide one half-day of training each week. At the weekly meetings, additional lessons are presented to help aides with the problems they encounter.

Volunteer leaders working with low-income youth and adults can also benefit from this training. Aides and volunteer leaders often work on the same type of program.

Scope of the lessons

Each lesson has a specific purpose. The 15 basic lessons provide aides with the information they need to begin the important job of helping families improve their diets. This initial training can also stimulate aides and leaders to want more information.

Lesson 1: Food Makes The Difference

Food's relationship to health and its meaning to people.

Lesson 2: Daily Food Guide

Daily Food Guide and how to use it.

Lesson 3: Key Nutrients

Important nutrients and their sources.

14509

Lesson 4: Foods Contain Different Amounts of Nutrients

Foods and the variation in the amounts of nutrients they contain.

Lesson 5: How Your Body Uses Food

Use of food in the body related to energy, growth, maintenance and repair of body cells.

Lesson 6: Food Needs Throughout Life

Amounts of nutrients needed vary according to age, activity, body size and stage of growth.

Lesson 7: Feeding Young Children

Relation of nutrition to child growth and development.

Lesson 8: Plan Meals To Meet Family Food Needs

Use of Daily Food Guide in planning meals and snacks.

Lesson 9: Get More For The Food Dollar

Wise food selection, use of a shopping list, and ways of keeping records of food costs.

Lesson 10: Comparative Food Shopping

Comparison of choices available to food shoppers.

Lesson 11: Preparation of Milk and Milk Products

Basic principles of milk cookery and how to apply them to preparation of milk and cheese dishes.

Lesson 12: Preparation of Vegetables and Fruits

Importance of fruits and vegetables in family meals. Understand and apply principles of vegetables preparation.

14509

14510

Lesson 13: Preparation of Meats

Review the foods that make up the meat group. Learn basic principles of meat cookery.

Lesson 14: Preparation of Breads and Cereals

Identify foods in the bread and cereal group. Understand and apply the principles of bread and cereal cookery.

Lesson 15: How To Take A Twenty-Four Hour Dietary Recall

Meaning and purpose of the 24-hour dietary recall. The technique of taking a recall.

Ideas for supplemental lessons to follow the 15 basic lessons in nutrition are suggested with each lesson plan. These additional lessons increase the knowledge of aides and leaders. It will also be necessary to repeat the basic lessons during the weekly in-service training meeting and apply this information to the problems that aides have identified.

References are suggested for the trainer agent with each lesson. It is essential that these references be assembled before starting the course. References are also suggested for the aides. Plan to order these well in advance.

It is important that the trainer agent be selective in the references she gives to aides. Review contents before giving them to aides. Go over references thoroughly with aides so that they know what is in each one.

Professionally-trained people in related fields may be asked to participate in training meetings. For example, a public health nutritionist would be helpful in the lesson on feeding young children.

Adapting the lessons to your aides

Just as it takes time for aides to develop good working relationships with homemakers, trainer agents need time to get to know the aides with whom they work. During the initial training period, you are presenting material and you are also

14511

trying to establish a working relationship with each aide. Effective communications can be vital to the success of the program.

These classes may be a new situation for many aides. They might need help in understanding why classes are necessary. They may wonder how much they will be asked to participate. You can discuss these matters with the aides and make them feel more comfortable in the classroom situation.

Discuss training plans with the aides. Tell them what they will be learning during the next few weeks. It is important that the aides feel that this is their training and their program, not just yours.

Adapt training classes to meet the needs of your group. Here are some ideas to keep in mind:

1. Simplify. Do not try to cover too much material in one lesson. Pick out the most important points and emphasize these.

2. Use colorful visuals and a dynamic presentation to help make the lesson more appealing.

3. Demonstrate ways of preparing foods. This method may be especially good for creating interest and stimulating discussion.

4. Tasting foods provides aides with ideas that they can pass along to other homemakers. Make sure the aides know how to prepare and serve donated foods if they are available.

5. Emphasize the good nutrition found in the food the aides are now eating. Point out how small changes can often result in a more balanced diet.

6. Stress foods rather than just nutrients.

7. Involve the aides in the training meetings in as many ways as possible.

Trainer agent's responsibility for aide training

These 15 lesson plans were written primarily to help trainer agents prepare new aides for work with families in

14512'

the Food and Nutrition Education Program. Aides must have a broad perspective on food and nutrition before they can begin to do their job. This is your responsibility.

Before the aides are trained and ready to go to work, trainer agents must develop working relationships with community agencies and organizations in relation to this program. Many low-income families have been in contact with agencies. These agencies and their field workers should know the Extension aide's function. If they believe that Extension aides can help families, they will be more apt to support the program and the aides. Community support is vital to the effectiveness of the Food and Nutrition Education Program.

Use this check list to make sure that you are ready to begin teaching:

___Meeting place with necessary facilities has been obtained.

___All the references you need to prepare the lessons have been assembled.

___Local public health service and library have been checked for additional references.

___All visual materials and equipment needed to teach the 15 lessons are on hand.

___All reference materials needed for the aides have been obtained.

___All lesson plans have been carefully studied so that you fully understand the overall content of the course.

___Sufficient time has been allowed to prepare each lesson.

Extend information

Much time and effort is involved in training aides. Make the most of the lessons you prepare by using this material in other ways. Use it to train volunteer leaders. Adapt it for use in newsletters or newspaper articles. A series of radio or TV programs based on the lessons could help to extend the ideas that aides are promoting to a larger audience.

Food recall information obtained from low-income families is used for reporting purposes. It should also be used to

14513

209 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

identify the food practices of families you are reaching, to evaluate the progress of your program, and to strengthen your aide training program.

Recognize achievement

Aides and leaders who complete the basic training course should be recognized. This is an achievement. A certificate gives aides something they can take home and show the family. Graduation dinners or special meetings are also a good idea.

Recommended publications, visual materials

For trainer agents, aides and leaders

Publications and visual materials are listed with each lesson. Make sure that these supplies are on hand before you begin teaching.

USDA

Single copies or bulk quantities of these USDA pamphlets can usually be obtained through your State distribution officer. USDA slide sets may be purchased from the Photography Division, Office of Information, U.S. Department of Agriculture, Washington, D.C. 20250.

APPENDIX B

PRESS RELEASE FOR COURSE PROMOTION

From: Centerville Central School

Contact Person: Carl Clum, Director of Adult Education

School Telephone: WH3-0001

Home Telephone: WO7-5464

Release Date: Immediate

EARN MONEY DOING GARMENT ALTERATIONS

Garment Alterations, a new course, will be offered by the adult education program of the Centerville Central School District.

The course will prepare individuals to alter ready-to-wear garments in a department store, specialty shop or their own business. Applicants must be able to use a sewing machine and a commercial pattern. Only persons with some basic sewing skills should apply due to the specific nature and limited time for training. Individuals should bring to the first class meeting a garment having a collar and set-in sleeves.

Instruction is designed to help each participant reach his full potential through group instruction and individual assistance.

Classes will begin Tuesday evening, September 24, at the Centerville High School and will run for fourteen weeks. Sessions will be held on Tuesday and Thursday evenings from 7 to 10 p.m.

Mrs. Evelyn Black, a home economist with many years of commercial experience in the clothing field, will be the instructor. Mrs. Black was recently chairman of the committee Expanding Job Potentials for Women sponsored by the Job Development Authority.

Enrollment will be limited to 15; therefore, prompt registration is necessary. A registration fee of $5.00 plus a materials fee of $3.00 will be charged.

To register or obtain further information, call Carl Clum, Director of Adult Education, at the school telephone number WH3-0001.

14523

Lesson 1: FOOD MAKES THE DIFFERENCE

PURPOSE

Trainer agent to help aides:

1. Understand how food affects the way a person feels, looks, and acts.

2. Understand factors that affect the food a person eats.

3. Learn to write a 24-hour dietary recall.

PRESENTATION

. Discuss the meaning of food.

Write the word "food" on the board. Have each aide write down five words (adjectives or nouns) that describe food. Discuss the different meanings of food. Divide words into "negative" and "positive" connotations.

The fact that food means something different to each person is related to a difference in values.

. Discuss the social, psychological, and physiological aspects of food.

-- Food satisfies hunger and other needs.

-- An adequate diet helps us resist disease.

-- Food gives us energy and strength.

-- Food affects mental performance.

-- Food is a part of social functions.

-- Food is used to express feelings, relieve tension.

-- Food is sometimes used as a bribe.

-- Food is used to express creativity.

14524

- Write twenty-four hour dietary recall.

  Have each aide write down the foods she ate in the last 24-hour period, including all meals and snacks. Use standard dietary recall method (See Lesson 15).

  (Trainer agent will later summarize 24-hour recall of aides as basis for understanding their food habits. This information should be compared with findings from a second 24-hour dietary recall at end of initial training.)

- Discuss how food affects the way a person grows, feels, looks, and acts. Show "How Food Affects You" slide set.

  --Food affects growth, bones, teeth, muscles, nerves, blood, skin, and eyes.

  --Nutrients are substances necessary for life. Food is made up of many nutrients.

  --Nutrition is the food you eat and how your body uses it.

  --Nutrition is not the only factor that influences health.

- Introduce "How Food Affects You" flipchart to aide.

APPLICATION OF LESSON BY AIDES

This lesson is an introduction to a series of background nutrition lessons set up primarily for the aide's information.

The lesson is designed to help aides understand the different attitudes towards food that they will encounter in their work.

The lesson introduces aides to the 24-hour dietary recall which they will be taking from homemakers.

-- Evaluating cultural food patterns

-- Superstitions about foods

-- Dietary recall

14526

Lesson 2: DAILY FOOD GUIDE

PURPOSE

Trainer agent to help aides:

1. Understand Daily Food Guide and how to use it.

2. Learn that all persons need foods from the four groups but in varying amounts.

3. Learn to evaluate food intakes.

PRESENTATION

- Give a quiz to determine nutrition knowledge of the aides. (See quiz, pp. 22-24.)

- Discuss the fact that no one food contains all the nutrients we need--a variety of foods is necessary.

- Explain the Daily Food Guide, using a mounted Daily Food Guide, flannelboard and food models.

  -- As each food group is discussed, have aides name foods in that group. Using the food models, place these on the flannelboard.

  -- Rearrange foods on the flannelboard to show the number of servings of each food group required daily. Discuss serving sizes. Actual portions of food could be shown. For example, a "glass" of milk using various size cups.

  -- Fats, salad dressings, etc., are "other" foods, not mentioned in the Daily Food Guide.

  -- Hand out notebook-size Daily Food Guide. Stress that this is easy method to help people plan meals so that everything the body needs is included.

14527

- Evaluate 24-hour dietary recall taken previously. Using Daily Food Guide, ask aides how they rated on the basis of:

  One serving from each food group.

  Recommended number of servings from each food group.

- Have available magazine pictures of various foods. Aides will group these into the four food groups. Place them on flannelboard and review each food group.

- Have aides role-play using the Daily Food Guide in a teaching situation.

- Review Eat To Live Better bulletin. Hand out Nutrition--Food at Work for You and briefly discuss.

APPLICATION OF LESSON BY AIDES

- Aides understand how to use the Daily Food Guide with homemakers.

- Aides may wish to make their own version of the Daily Food Guide using local foods. For example, a file folder can be divided into four parts. Magazine pictures of foods from the four food groups can then be placed in the appropriate sections for use in discussions with homemakers.

Lesson 2

NUTRITION QUIZ

Some statements about nutrition are given below. Please show whether or not you think each statement is correct or false. Circle "T" for true and "F" for false. If you don't understand a statement, ask your Trainer Agent about it. If you are completely unsure of the answer, circle both "T" and "F".

	True or False
1. Good eating habits are important to health.	T F
2. In a family, including a father, mother, 16-year old son and an 18-year old daughter, the father should have the largest serving of meat.	T F
3. Protein-rich foods, such as meat, milk and eggs, provide liberal amounts of several nutrients needed for the growth of small children.	T F
4. It is better not to include orange juice and milk in the same meal because orange juice causes the milk to curdle in the stomach.	T F
5. By the end of the first year, babies should have learned to use a variety of foods besides milk, as a milk diet may not allow for total growth and development.	T F
6. School age children need vitamin pills to ensure good health.	T F
7. The term "well-balanced" when applied to a day's diet means that all of the food groups in the daily plan are included in amounts recommended.	T F
8. A serious vitamin deficiency may affect many parts of the body.	T F
9. When children have enough food to satisfy their appetites, their diets are certain to be nutritionally adequate.	T F

14258

14530

10. A good nutritional practice is to eat a variety of foods each day. T F

11. Eggs can completely replace milk in the diet so far as nutrients are concerned. T F

12. Carbonated beverages are a desirable food for young children. T F

13. Skim milk contains the same amounts of body building minerals and protein as whole milk. T F

14. No reducing diet should contain bread or potatoes. T F

15. Most fat children and overweight adults have a glandular disturbance. T F

16. Milk is a food mainly for infants and growing children. T F

17. Apples are an excellent source of Vitamin C. T F

18. Foods that taste sour are generally not good for people. T F

19. Foods enriched with Vitamin D can help in the normal development of bones and the prevention of rickets. T F

20. All people should use a low-fat, low cholesterol diet to prevent heart disease and strokes. T F

21. If a person eats regular meals, he should be rated as having good food habits. T F

22. A "well-balanced" meal is one that is not too starchy or too fat. T F

23. The greater the percentage of polyunsaturated fats in a food, the greater the health-giving properties of that food. T F

24. The four groups of foods in the daily food guide are Dairy Foods, Meats, Citrus Fruits, and Cereals. T F

14531

25. Healthy, active, young children require some concentrated sweets in their diet each day for energy needs. T F

This material is based on a test developed by the Department of Food and Nutrition, Iowa State University, Ames, Iowa.

14531

14532

Lesson 3: KEY NUTRIENTS

PURPOSE

Trainer agent to help aides:

1. Define nutrients.
2. Understand the relationship of nutrients to health.
3. Become familiar with important food sources of the key nutrients.

PRESENTATION

- Explain the meaning of nutrients.
- Review the leaflet, Key Nutrients.
- Show flip chart and selected slides from "How Food Affects You" slide series.
- Give an over-all view of how nutrients relate to four food groups:
  - what does each nutrient do in the body?
  - what are good food sources of the nutrients?
  - what amounts of each food are needed to supply recommended nutrients?
- Have aides use food models or pictures to illustrate good food sources of each nutrient.

APPLICATION OF LESSON BY AIDES

Reproduce page 8, titled "What Good Foods Can Do For Us", from the leaflet Food for Families. Explain to aide how she can use this in teaching situations.

Show aides how they can relate nutrients to foods when they talk with homemakers.

14533

REFERENCES FOR TRAINER AGENT

1. Food for Families, Suggestions for Trainer Agent, PA-743, USDA.

2. Nutrition--Food at Work for You, GS-1, USDA.

VISUALS AND EQUIPMENT

Flannel board, food models, and pictures.

"How Food Affects You" slide series and flip chart, USDA.

Slide projector and screen.

REFERENCES FOR AIDES

Key Nutrients, PA-691, USDA.

EVALUATION

Use pictures of nutrients from How Food Affects You flip chart and have aides match to food pictures.

IDEAS FOR SUPPLEMENTAL LESSONS

Protein, carbohydrates, fats and water

Calcium and iron

Vitamins

14233

14534

Lesson 4: FOODS CONTAIN DIFFERENT AMOUNTS OF NUTRIENTS

PURPOSE

Trainer agent to help aides:

1. Learn that many nutrients are necessary to meet needs of the body.

2. Understand that nutritive values are different for each food.

3. Realize that nutrients for body needs are easy to obtain when a variety of foods are eaten.

PRESENTATION

- Use Comparison Cards for Adults (National Dairy Council) to show the differences in nutrient value of various foods.

- Comparison cards show the percentage of the daily requirement for key nutrients that various foods provide. Have aides divide cards into the four food groups and select foods and combinations of foods that will meet 100 percent of the daily requirement for that nutrient.

- Using comparison cards, show sources of protein, Vitamins A and C, calcium, and iron. For example, note the protein in meat, milk, breads, and cereals. The following question may be used to involve aides in the discussion: "If I needed to get more Vitamin A and ascorbic acid in my diet, which vegetable would be the best choice—green beans, potato or sweet potato?"

- Discuss other references containing information on nutritive value of foods. For example - Nutritive Value of Foods.

14536

14535

APPENDIX D

GUIDE SHEET FOR BURNING TEST†

Name_____ Date_____

Materials Required

- Matches
- Candle (food warmer)
- Small aluminum pie tin
- Strip of aluminum foil
- Tweezers
- Packet of fabric samples
- Information Sheet - Burning Fiber Characteristics

Directions

(1) Place all the equipment on the strip of aluminum foil.
(2) Place the candle in the small pie tin.
(3) Light the candle and using the tweezers, hold each fabric sample in the flame.
(4) Observe and record in the appropriate places the appearance of the flame, the odor, and the ash of each fabric.
(5) Identify each sample by comparing the recorded observations with the data given in the Information Sheet - Burning Fiber Characteristics.

FABRIC NUMBER AND DESCRIPTION	APPEARANCE OF FLAME	ODOR	ASH	YOUR IDENTIFICATION OF THE FIBER

† Adapted from Cozine, June, & others. *A pilot study for gainful employment in home economics.* Washington, D. C. U.S. Government Printing Office. 1968.

1451

APPLICATION OF LESSON BY AIDES

Aides understand how to use comparison cards in teaching situations to illustrate that foods contain different amounts of nutrients.

REFERENCES FOR TRAINER AGENT

1. Eat to Live Better, PA-694, USDA.
2. Nutritive Value of Foods, G-72, USDA.
3. Composition of Foods, Handbook No. 8, USDA.
4. Food For Us All, Yearbook of Agriculture, 1969, pp. 315-318, USDA.

VISUALS

Comparison Cards for Adults and Teaching Guide (National Dairy Council).

REFERENCE FOR AIDES

Comparison Cards for Adults (National Dairy Council).

EVALUATION

Observe aides' ability to solve the following problems:

1. Can cottage cheese take the place of milk? Can ice cream? What role do these foods play in menus?
2. If I want to serve eggs or cheese as an alternate for meat, how many eggs or how much cheese should I substitute for one serving of meat?
3. Why should an iron-rich food be included in the day's menu if cheese is used as a main dish?

IDEAS FOR SUPPLEMENTAL LESSONS

Meat and meat substitutes as sources of protein.

Fruits and vegetables rich in vitamins and minerals.

Breads and cereals for energy foods.

Dairy foods supply calcium, protein, and riboflavin.

14235

14536

Lesson 5: HOW YOUR BODY USES FOOD

PURPOSE

Trainer agent to help aides:

1. Review and gain additional knowledge of how the body uses food for energy, growth, maintenance, and repair of body cells.

2. Understand that all foods can be classified as protein, carbohydrates, or fat.

PRESENTATION

- Show the first 40 frames of "How Food Becomes You" filmstrip.

- Review and summarize all lessons covered previously, placing emphasis on the relationship of food to a healthy body.

- List and discuss how the body uses:

  - protein foods to build and repair the cells of the body.

  - carbohydrate foods for energy to live, work and play. Compare number of calories used in various activities; such as sleeping, eating, walking, and others.

  - fats for heat and energy.

  - minerals for formation of bones, teeth and many other functions.

  - vitamins for growth, to prevent disease, and to keep the body functioning properly.

  - water to regulate body temperature and to carry nutrients to cells.

14537

- Show that all foods may be classified as protein, carbohydrates, and fats and all supply energy in varying amounts. Vitamins, minerals, and water are found in combinations in these classes of food.

- Energy is expressed in terms of calories. Use Comparison Cards to show calories and nutrients in foods.

APPLICATION OF LESSON BY AIDES

This lesson is designed as background information for aides so that they can help homemakers understand the importance of eating a wide variety of foods.

REFERENCES FOR TRAINER AGENT

1. How Your Body Uses Food, National Dairy Council.

2. Food and Your Weight, G-74, USDA.

3. Calories and Weight, G-153, USDA.

VISUALS AND EQUIPMENT

"How Food Becomes You" filmstrip, National Dairy Council.

Comparison Cards For Adults, National Dairy Council.

Projector and screen.

REFERENCES FOR AIDES

How Your Body Uses Food, National Dairy Council.

EVALUATION

Have aides respond orally to questions taken from main points covered in first five lessons.

IDEAS FOR SUPPLEMENTAL LESSONS

Digestion and absorption of food in the body.

14237

14538

Lesson 6: FOOD NEEDS THROUGHOUT LIFE

PURPOSE

Trainer agent to help aides:

1. Understand that throughout life the same nutrients are needed but differences in age, activity, size, and stages of growth affect the amounts needed.

2. Know the food needs of people at different stages in life.

3. Understand that individual food needs vary.

PRESENTATION

- Show pictures illustrating people in the different stages of life. Ask aides to tell what foods they believe adult men and women, pregnant women, children at various ages, and older folks need.

- Use Daily Food Guide and discuss changes in food required for different activities and stages of growth:

  -- Adult men and women
  Amounts of foods recommended by the Daily Food Guide plus added foods for energy needs.

  -- Pregnant women
  Amounts of foods recommended by the Daily Food Guide plus additional milk and selection of additional foods from the four food groups. Additional calories are needed only in the second half of pregnancy.

  -- Children
  The foods recommended in the Daily Food Guide but smaller servings. Additional foods from the four food groups if needed for energy.

  -- Teenagers
  The foods recommended in the Daily Food Guide plus additional milk and additional foods from the four food groups to meet energy needs.

14540

14539

-- Older folks

The foods recommended in the Daily Food Guide. Fewer additional calories because activity is less.

REFERENCES FOR TRAINER AGENT

1. Food For Us All, Yearbook of Agriculture, 1969, "A Food Guide for the Ages, From Baby to Gramps," pp. 294-303, USDA.

2. Daily Food Guide, C&MS-23, USDA.

VISUALS AND EQUIPMENT

Flannelboard and blackboard or newsprint.

Pictures of persons at various stages in life.

Descriptions of people at various stages in life, written on slips of paper.

REFERENCES FOR AIDES

Food For Fitness, L-424, USDA.

EVALUATION

Trainer agent provides slips of paper describing people of different ages, body sizes, and activities. Aides are asked to draw a slip and give the food needs of that person.

IDEAS FOR SUPPLEMENTAL LESSONS

Food Needs At Different Ages

the infant and preschool child
the school age child
the teenager
the pregnant and nursing woman
older folks
other special food problems

14540

14539

Lesson 7: FEEDING YOUNG CHILDREN

PURPOSE

Trainer agent to help aides:

1. Understand that most food habits are formed during childhood.

2. Understand the relation of nutrition to growth and development of the child.

3. Encourage parents to help children develop desirable food habits.

PRESENTATION

- Show "Feeding Your Young Children" filmstrip.

- Review important points on blackboard or sheet of newsprint.

  -- Importance of food for growth and development

  All nutrients are in food.
  No food contains all nutrients.

  -- Characteristics of a well-nourished child.

  Body build and growth rate.
  Hunger and appetite.
  Desirable weight.

  -- Developing good food habits.

  Experiences with the wide variety of foods.
  Providing favorable conditions.
  Positive attitude of parents.
  Coping with eating problems.

- Introduce Feeding Young Children bulletin. Discuss content. Also introduce and discuss Your Child From One to Six, Feeding Little Folks and Food Before Six.

14541

- Acquaint aides with local resources that offer related services to children and parents. For example, school feeding programs, baby clinics, children and youth projects, crippled children's clinics, etc.

APPLICATION OF LESSON BY AIDES

Have aides share and discuss ways they see they could use this information in working with parents to help children develop desirable eating habits.

REFERENCES FOR TRAINER AGENT

1. Feeding Young Children, PA-693, USDA.

2. Folders available from local health department or Office of Child Development, U.S. Department of Health, Education and Welfare. For example: Your Child from One to Six - No. 30.

3. Feeding Little Folks and Food Before Six, National Dairy Council.

4. Feeding Your Baby and Child, Spock and Lowenberg, Chapter VI, "Setting the Stage for Children's Eating."

5. Food for the Family with Young Children, G-5, USDA.

VISUALS AND EQUIPMENT

"Feeding Your Young Children" filmstrip, National Dairy Council.

Listing of local resources.

Blackboard or newsprint.

Projector and screen.

REFERENCES FOR AIDES

1. Feeding Young Children, PA-693, USDA

2. Feeding Little Folks, National Dairy Council.

14541

14542

EVALUATION

Observe aides' attitude toward several of the following statements:

"Carrots will make you pretty." (False Reason)

"If you don't eat your egg, you can't have dessert." (Threat)

"A bite of food you like after the new foods helps." (Suggestion)

"You're getting along fine without any help." (Independence)

IDEAS FOR SUPPLEMENTAL LESSONS

Introducing new foods.
Kind and amount of food a child needs at different ages.
Coping with eating problems.

14543

Lesson 8: PLAN MEALS TO MEET FAMILY FOOD NEEDS

PURPOSE

Trainer agent to help aides:

1. Obtain an overview of planning food for family meals and snacks.

2. Appreciate the value of advanced planning.

PRESENTATION

- Introduce lesson by placing food models for a day's meals and snacks on a flannelboard. These meals may or may not be adequate. Have aides separate foods into the four food groups. If the meals do not meet the recommendations of the Daily Food Guide, ask the aides to suggest foods to add so that the day's intake in each of the four food groups is complete.

- Discuss the importance of eating a variety of foods spaced throughout the day in meals and snacks. There are physiological benefits. For example: breakfast eaters have been shown to be more alert, steadier, and more productive in the late morning hours than breakfast skippers.

- Discuss different patterns of eating. There are different patterns of eating that help us distribute the nutrients we need throughout the day. These patterns are only a guide and can be adjusted to suit different family situations. An example can be illustrated with food models on flannelboard.

Breakfast:	Fruit or juice, bread or cereal, milk, beverage.
Lunch:	Main dish, vegetable or fruit, bread, milk (a good time for adults to get milk).
Dinner:	Main dish, two vegetables, bread, beverage, dessert (fruit makes a good dessert).

14543

14544

- Snacks should help us meet our daily needs for nutrients.
  - -- Show how food in the three meal a day pattern can also be used as snacks.
  - -- Show how teenagers can get adequate servings from the milk group in snacks.
  - -- Choose snacks from the Daily Food Guide. Compare the food value in empty calorie snacks (candy and carbonated drinks) and nutritious snacks (fruit, milk, fruit juices.) Use Comparison Cards.
- Introduce and discuss Meal Planning Made Easy leaflet.
- Discuss value of advanced planning for food for the family.
  - -- Can help save time and money.
  - -- Makes it easier to follow the Daily Food Guide.
  - -- Makes it easier to provide variety in family meals and snacks.
- Discuss points to consider when planning meals.
  - -- Suit planning to your situation.
  - -- Have tools available to help -- paper, pencils, Daily Food Guide, meal patterns.
  - -- Plan food for a day as a unit.
  - -- Consider age and activity of family members.
  - -- Plan for color, texture, shape, and flavor. This will add interest to meals. Illustrate with actual foods or pictures.

APPLICATION OF LESSON BY AIDES

Aides understand how to use information in teaching situations and in own family meal planning.

14545

INFORMATION SHEET - BURNING FIBER CHARACTERISTICS			
FIBER	FLAME	ODOR	ASH
ACETATE	Flames quickly; material puckers, sputters, melts; drips like tar	Acid, like vinegar	Brittle black ash, difficult to crush with fingers
ARNEL	Flames quickly; sputters, melts; drips like tar	Acid, like vinegar	Like acetate
COTTON	Large yellow flame; burns quickly, leaves creeping ember	Like burned paper	Light, feathery, grayish ash; black ash denotes mercerized cotton
CRESLAN	Melts	Acrid	Hardens
DACRON FORTEL KODEL VYCRON	Melts before burning; burns slowly	Slightly sweetish, aromatic	Brittle, beady ash, creamy in color
DARVAN	Melts and burns		Hard black bead
DYNEL	Shrinks; will not support combustion	Disagreeable	Hardens; becomes brittle
FIBERGLASS	Will not burn; melts at temperature over 1,500° F.		Melts
LINEN	Like cotton; sometimes burns slower if yarn is heavier, leaves creeping ember	Like burned paper	Like cotton; sometimes heavier if yarn is thicker
METALLICS	Only other fibers in fabric burn		Metal ribbons
NYLON	Melts, shrinks from flame; bubbles as it burns	Pungent acrid odor	Hard round amber beads, cannot be crushed

VISUALS AND EQUIPMENT

Food models (National Dairy Council).

Flannelboard.

Pictures or actual foods to illustrate ways of getting variety in meals.

Comparison Cards for Adults (National Dairy Council).

Daily Food Guide poster, C&MS-23, USDA.

REFERENCES FOR AIDES

Meal Planning Made Easy, PA-695, USDA.

Guide To Good Eating, National Dairy Council.

EVALUATION

Have each aide plan meals for her family for one day using the Daily Food Guide and meal patterns which are best for her situation.

IDEAS FOR SUPPLEMENTAL LESSONS

It's what you eat - not how or when.

Snacks as a part of your day's food plan.

Meal planning for young children.

Meal planning when a baby's on the way.

Meal planning when there's a calorie counter in the family.

Meal planning when older folks are with you.

14546

Lesson 9: GET MORE FOR THE FOOD DOLLAR

PURPOSE

Trainer agent to help aides:

1. Identify factors that influence food selection.
2. Learn the value of making shopping lists.
3. To learn how to keep simple food record costs and make use of this information.

PRESENTATION

. Discuss factors that influence food selection.

-- Money available.
-- Size, age, and activities of family members.
-- Storage and equipment.
-- Food likes and dislikes.
-- Season and locality.
-- Special diets.
-- Time for preparation.
-- Availability of stores in which to shop.

. Show "Selecting and Buying Food for the Young Family" slide series. As the slides are shown, look for some of these points.

-- Needs of different family members.
-- Steps in making a shopping list.
-- Ways to save money in shopping.
-- Ways to store food.
-- Family values.

. Discuss slide set.

-- What factors determine the food needs of different family members?

Sex
Activities
Age

14547

-- What steps were suggested for making a shopping list?

Think through meals to be prepared.
Check what is on hand.
Plan around the four food groups.

-- What ways were suggested for saving time?

Consider convenience foods.
Plan ahead.
Shop when store is not crowded.

-- What ways were suggested for saving money? Add ideas you have used.

Check newspaper ads.
Separate food from nonfood items.
Avoid impulse buying.
Consider specials.
Check price per serving.
Consider convenience foods.

-- How was it suggested that foods should be stored?

Frozen foods and ice cream -- in freezer if possible.
Meat and poultry -- loosely wrapped and put in coldest part of refrigerator.
Sugar, flour, rice, dry milk -- use canisters, cans, or jars with tight fitting lids to keep foods dry and free from insects.

. Discuss food cost records.

-- Ask aides how much money they think they spend for food.
-- Ask aides how they know how much money they spend.
-- Discuss ways shoppers can know how much money they spend for food.

Keep shopping list and cash register receipts. (Deduct nonfood items)
Allotment of certain amount of income for food.
From total money spent for food, subtract 25 percent for nonfood items.

14547

14548

-- Discuss value of food cost record and how it can be used to get more for the food dollar.

. Introduce Family Fare bulletin. Discuss contents and use.

. Summarize lesson:

-- Selecting and buying food to nourish the family adequately for good health at a price she can afford is a big challenge for any homemaker. Keeping a record of money spent for food is a good starting point for studying food buying practices.

APPLICATION OF LESSON BY AIDES

Aide will use this knowledge in obtaining information for the Family Record - Part 2, and to help homemakers get more for their food dollar.

Improve food buying practices.

Selecting and Buying Food, PA-696, USDA.

14549

14220

EVALUATION

Aides keep a food cost record so that it can be analyzed and discussed at a later time.

IDEAS FOR SUPPLEMENTAL LESSONS

Buying and storage of food.
Buying meats.
Buying fruits and vegetables.
Buying dairy products.
Buying cereals.

14249

14550

Lesson 10: COMPARATIVE FOOD SHOPPING

PURPOSE

Trainer agent to help aides:

1. Become more aware of the way food items are grouped in different stores.

2. Learn how to read labels.

3. Compare cost, form, quality, and nutritive value of foods.

4. Become aware of special services provided by food stores.

PRESENTATION

Divide aides into groups of 2-4 to visit food stores. This can be done on the day before the meeting on Comparative Shopping, or it can precede the meeting. Assign these topics to groups. Ask them to compare cost per unit, cost per serving, form of food available and nutritive value.

-- Cereals - presweetened
cornflakes
highly fortified cereal
oatmeal - instant
old fashioned
quick.

-- Milk - fresh whole, 2% skim, non-fat dry, evaporated.

-- Cheese - mild, sharp, process, process cheese spread.

-- Eggs - size and grade.

-- Ground meat - ground beef
ground round
ground chuck.

14551

-- Vegetables - fresh, frozen, canned green beans.

- Aides will report on their visits to food stores.

- Trainer agent will bring food advertisements to class for aides to study. Discuss the following:

  Are advertised foods really a bargain?
  Why are some foods advertised as being on special?
  What information is given about specials?
  Where can you find food advertisements?
  What differences or similarities are found among food advertisements?

- Compare quality and cost of food. Examine contents of three different cans of green beans. Compare taste, texture, color. Note broken pieces, amount of liquid, discoloration. Compare cost.

- Discuss and study labels:

  a. Required information
  b. Other information
  c. How to use information on label

- Have aides report on special services found in stores visited. Discuss how stores are arranged for convenience and promotional products.

APPLICATION OF LESSON BY AIDES

Aides use information to help homemakers become better food shoppers.

REFERENCES FOR TRAINER AGENT

1. Consumers All, Yearbook of Agriculture, 1965, pp. 416-440, USDA.

2. Handbook of Food Preparation, pp. 9-20, American Home Economics Association.

14551

14552

4. It's on the Label, National Canners Association.

5. Food For Us All, Yearbook of Agriculture, 1969, pp. 45-50, USDA.

VISUALS AND EQUIPMENT

Cans of food, dishes for display.

Labels

Food advertisements

REFERENCES FOR AIDES

How to be a Better Shopper, Sperry and Hutchinson.

Family Fare, G-1, USDA.

EVALUATION

Ask aides to give two examples of good food buys they have made and tell why they were good buys.

IDEAS FOR SUPPLEMENTAL LESSONS

Buying selected food items.
Reading labels.
Tour of markets.
Selecting food for quality.

14553

Lesson 11: PREPARATION OF MILK AND MILK PRODUCTS

PURPOSE

Trainer agent to help aides:

1. Appreciate the need for milk at all ages.
2. Learn principles of milk cookery.
3. Apply principles in preparation of milk and cheese dishes.

PRESENTATION

- Review the importance of milk.
  - -- Everyone needs milk.
  - -- Children under 9 years of age need 2 to 3 cups a day. Some children do not have the capacity to drink this much. Some of it can be used in cooked foods.
  - -- Teenagers need four or more cups a day.
  - -- Adults of all ages need at least two cups a day. Older folks need milk to supply calcium for bone strength and protein for tissue repair. Milk is easily digested by most people.
  - -- Pregnant women need three or more cups.
  - -- Nursing mothers need four or more cups a day.
- Display different forms of milk and some popular types of cheese. Discuss.

14553

14554

- Review the principles of milk cookery.

  Use low heat in cooking because milk scorches easily. Milk can be heated satisfactorily over low direct heat or over boiling water. (Demonstrate)

  Natural cheese should be heated at a low temperature to prevent it from getting stringy or tough. (Demonstrate) Processed cheese melts more easily and is less likely to get stringy when heated at high temperatures because an emulsifying agent has been added.

- Discuss storage:

  -- Fresh dairy products are highly perishable. Keep them clean, cold, and tightly covered.

  -- Refrigerate fresh milk, cream, and milk products as soon as possible after purchase. If milk stands in the sunlight, riboflavin is lost and the flavor changes.

  -- The numbers of bacteria increase as milk ages or stands at room temperature. Milk which has been taken from the carton should not be returned to it.

  -- Keep unopened cans of evaporated milk at room temperature or in a cool place. Once opened, refrigerate.

  -- Store cheese covered in the refrigerator. Cheese mold is not harmful.

  -- Store nonfat dry milk in tightly covered containers in a cool place. After dry milk is reconstituted, treat it as fresh milk.

- Demonstrate uses.

  Dry milk can be used in two ways. It may be reconstituted and used as fresh fluid milk or it may be mixed with dry ingredients. Demonstrate both.

14555

22 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

List some ways milk and milk products can be used for soup, main dishes, desserts, beverages, and snacks.

Divide aides into small groups and prepare low cost milk and cheese dishes. Plan a meal around these foods.

Demonstrate whipped toppings for desserts made with dry and evaporated milk.

APPLICATION OF LESSON BY AIDES

Aides encourage families to use more milk and milk products.

Aides apply principles of milk cookery in teaching situations.

REFERENCES FOR TRAINER AGENT

1. Food for Us All, Yearbook of Agriculture, 1969, pp. 146-159, USDA.

2. Consumers All, Yearbook of Agriculture, 1965, pp. 437-440, USDA.

3. Milk in Family Meals, G-127, USDA.

4. Cheese in Family Meals, G-112, USDA.

VISUALS AND EQUIPMENT

Food and equipment for demonstration.

REFERENCES FOR AIDES

1. Milk in Family Meals, G-127, USDA.

2. Cheese in Family Meals, G-112, USDA.

EVALUATION

Have aides prepare a list of dishes made with milk or cheese that they could suggest to homemakers.

IDEAS FOR SUPPLEMENTAL LESSONS

Prepare other foods using milk and dairy products.
Discuss further uses of nonfat dry milk.
Prepare milk drinks.

14555

14556

Lesson 12: PREPARATION OF VEGETABLES AND FRUITS

PURPOSE

Trainer agent to help aides:

1. Review the importance of fruits and vegetables in family meals.

2. Understand and apply the principles of vegetable preparation.

PRESENTATION

. Show place of vegetables and fruits in Daily Food Guide.

-- All fruits and vegetables supply vitamins and minerals but in varying amounts. Use slides 19-29 from "How Food Affects You" slide series to illustrate.

-- Most dark green and deep yellow vegetables are inexpensive sources of Vitamin A. For example: greens, pumpkin, squash, sweet potatoes, and carrots. They are also sources of Vitamin C.

-- Many of them are low in calories. Raw vegetables are a low-calorie between-meal snack.

-- Dry peas and beans are high in protein. This is the reason they are placed in the meat group of the Daily Food Guide.

-- The Daily Food Guide recommends four or more servings of fruits and vegetables per day. Show serving size.

. Discuss principles of vegetable cookery.

-- Suggestions for preparation

14557

. Wash vegetables before cooking

. Trim and pare thinly to avoid excessive loss of nutrients

. Some vegetables may be cooked in their skins.

-- Basic methods of cookery

. Boiling - To insure the best flavor, color, texture, and food value, cook only until tender. Vegetables cooked in skins retain most nutritive value. To shorten cooking time, cut, slice, dice, or coarsely shred vegetables. Cooking in small amounts of water conserves nutrients.

. Baking - Bake in a hot oven (400-450°) so vegetable cooks in a short time. Moderate oven may be used but longer cooking time is needed.

. Frying - Vegetables may be pan-fried in small amount of fat or cooked in deep fat. Using the correct temperature for frying prevents the absorption of large amounts of fat.

-- Demonstrate the three methods. Discuss the advantages and disadvantages in relation to cost, time, color, flavor, texture, and nutritive value.

-- Have aides list as many ways as possible to prepare several low-cost vegetables such as potatoes, leafy greens, and corn.

-- Show selected frames from "Vegetable Treasure" filmstrip.

APPLICATION OF LESSON BY AIDE

Aides encourage families to use more fruits and vegetables.

Aides apply principles of vegetable cookery in teaching homemakers.

14557

14558

REFERENCES FOR TRAINER AGENT

2. Consumers All, Yearbook of Agriculture, 1965, pp. 454-456, USDA.

3. Vegetables in Family Meals, G-105, USDA.

4. Fruits in Family Meals, G-125, USDA.

VISUALS AND EQUIPMENT

Daily Food Guide poster, C&MS-23, USDA

"How Food Affects You" slide series, USDA.

"Vegetable Treasure" filmstrip, Green Giant Company. (Selected frames)

Projector and screen.

Food and equipment for vegetable preparation.

Comparison cards for adults, National Dairy Council.

REFERENCES FOR AIDES

1. Vegetables in Family Meals, G-105, USDA.

2. Fruits in Family Meals, G-125, USDA.

3. Principles of Cookery, PA-692, USDA.

4. Family Fare, G-1, USDA.

EVALUATION

Have aides try a new vegetable or cooking method and report to the group.

IDEAS FOR SUPPLEMENTAL LESSONS

Making salads with fruits and vegetables.
Preparing vegetable soup.
Cooking vegetables in tempting ways.
Using raw vegetables as snacks.

14559

14560

Lesson 13: PREPARATION OF MEATS

PURPOSE

Trainer agent to help aides:

1. Review the variety of foods included in the meat group.

2. Learn principles of meat cookery.

PRESENTATION

- Aides review the variety of foods included in the meat group: poultry, fish, eggs, dry beans and peas, peanut butter and meat. (Fat back, salt pork, and bacon are considered fats rather than meat.)

- Review the nutrients of foods included in the meat group.

- Identify the least costly sources of protein. Discuss extending food dollar by using eggs, cheese, milk, cereals, and vegetables.

- Discuss basic meat cooking methods.

  --Roasting
  --Broiling
  --Pan broiling
  --Pan frying
  --Braising
  --Cooking in liquid

- Review factors which affect the method selected: tenderness, size, thickness, amount of bone, desired flavor, available time and cooking facilities.

  Beef - Thick blocky cuts from the rib, loin, and sirloin usually are roasted. Choice grades chuck, round or rump can be oven-roasted. Lower grades make excellent pot roasts. Thin steaks usually are best pan broiled or pan fried; thick steaks are best broiled. Braising

14559

14560

or cooking in liquid are generally recommended for less tender cuts. Commercial meat tenderizers are best used with meats to be fried or broiled.

Pork - Selection of a cooking method for pork depends on the cut. Pork should be cooked medium or well done. Generally thick cuts are roasted, braised or simmered; thin cuts are pan broiled, pan fried, or braised.

Poultry - Age of the bird usually determines the method selected. Broilers and fryers are usually tender.

Variety meats (liver, kidneys, heart, tongue, and tripe). Type of cooking depends on how tender the particular meat is. These meats are usually cooked well done.

- Demonstrate several methods of cookery using low cost cuts of meat.

- Discuss storage - Fresh meat is highly perishable and must be refrigerated. Cooked meat should be covered, chilled and used as soon as possible.

APPLICATION OF LESSON BY AIDE

Aides use information in talks with and demonstrations for homemakers.

REFERENCES FOR TRAINER AGENT

2. Pork in Family Meals, G-160, USDA.

3. Money-Saving Main Dishes, G-43, USDA.

EVALUATION

Show filmstrip or pictures of meat cuts and ask aides to identify and suggest ways of cooking.

Encourage aides to check with homemakers to see if new meat cuts or methods of cookery have been used.

IDEAS FOR SUPPLEMENTAL LESSONS

Cooking variety meats.
Cooking beans, peas and lentils.
Use of peanut butter.
Meat-stretching ideas.

14561 14562

Lesson 14: PREPARATION OF BREADS AND CEREALS

PURPOSE

Trainer agent to help aides:

1. Review the foods in the bread and cereal group.
2. Learn some principles of bread and cereal cookery.
3. Know a variety of ways to prepare breads and cereals.

PRESENTATION

- Describe foods in the bread and cereal group. Illustrate using magazine pictures and flannelboard. Emphasize value of enriched and whole grain breads and cereals.
  - -- Breads can be divided into three general classes: unleavened, those leavened with yeast and those leavened with baking powder. Yeast breads are usually allowed to rise before they are baked whereas the carbon dioxide from doughs made from baking powder is released in the oven.
  - -- Cereals fall into three general classes: Those that are cooked and eaten hot, "instantized" cereals that only require the addition of boiling water, and those that are ready-to-eat as they come from the package.
- Explain some of the basic principles of bread preparation.
  - -- Yeast, a living plant, is easily injured by high temperatures. Liquids used to soften yeast must be at the required temperature.

14563

-- Flour provides the proteins that develop into gluten to form the cells, crumb and framework of breads.

-- Gluten develops with kneading, producing cells which then contain the leavening gas. Not all yeast-leavened breads must be kneaded. In batters and soft doughs, beating or stirring develops the gluten.

-- During the rising period, carbon dioxide gas and alcohol are formed by the yeast cells. Elastic gluten strands trap this leavening gas, allowing the dough to double or triple its bulk. Time needed for rising depends on the temperature, the amount of yeast used, the richness of the dough and the kind of flour used.

-- Too hot an oven can cause the crust of breads to form too fast. This limits the expansion of the leavening gas and the volume of the baked product.

-- If oven temperature is too low, breads do not rise quickly enough to set the gluten structure before water evaporates. This limits volume and allows the leavening gas to escape too soon, sometimes causing the bread to fall.

. Explain some of the principles of starch cookery.

-- In making gravy and sauces, the starch mixture should be heated long enough for the starch grains to take up water and swell, causing the thickening process to take place.

Prolonged boiling may cause starch paste to become thin because some of the starch converts to simple sugars.

Separate starch grains before heating by mixing with cold liquid, creamed or melted fat or sugar, to avoid forming lumps of cooked starch.

14564

- Explain some of the basic principles of cereal cookery.

  -- In cooking cereals, the most important nutrient loss is thiamine, which is subject to destruction by heat and is also soluble to water. Except for macaroni products, it is best to cook cereals and rice so that the water will be completely absorbed. Macaroni requires more water.

  -- Packaged cereals requiring cooking should not be washed. Washing once before cooking can cause a thiamine loss of 10 percent in brown and converted white rice and 25 percent in regular rice. Rinsing rice after cooking should also be discouraged.

- Demonstrate different ways to prepare and serve breads.

- Demonstrate a variety of ways to prepare and serve cooked cereals.

APPLICATION OF LESSON BY AIDE

Aides understand some basic principles of bread and cereal cookery.

Aides know a variety of ways to prepare breads and cereals.

Aides understand how to use this information in talks with homemakers.

REFERENCES FOR TRAINER AGENT

1. Food for Us All, Yearbook of Agriculture, 1969, pp. 205-225, USDA.

2. New Treasury of Yeast Baking, Fleischmann's.

14565

Information Sheet - Burning Fiber Characteristics (Continued)

FIBER	FLAME	ODOR	ASH
OLEFIN (Polypropylene, Polyethylene)	Fuses, shrinks, curls away from flame; melts as it burns	Polypropylene - faint asphalt Polyethylene - burning parafin	Hard, tough tan round bead
ORLON	Melts; burns like acetate; yellow flame, black smoke	Acrid	Hard black bead
RAYON	Ignites quickly, like cotton	Like burned paper	Like cotton
ROIME JUTE	Yellow flame, smolders with creeping ember	Burning paper	Small fluffy gray ash
SARAN	Melts, shrinks from flame; not flammable		Hard bead
SILK (Pure dye)	Burns slowly; ceases flaming when withdrawn from flame	Animal odor, less pronouned than wool	Round, crisp, shiny black beads, easily crushed with fingers
SILK (Weighted)	No flame; burned part becomes incandescent and chars	Same as pure silk	Screenlike skeleton of original sample
SPANDEX	Fuses but does not shrink away from flame; burns with melting	Musty	Leaves a soft fluffy, gummy ash
VEREL	Melts; shrinks from flame	Acrid	Hard black ash
VICARA	Somewhat like wool	Burning chicken feathers	Small bead, easily crushed
WOOL	Small, slow flickering flame; sizzles and curls	Strong animal odor like burning feathers or hair	Crisp dark ash, irregular shape, easily crushed with fingers
ZEFRAN	Flames; sputters slightly	Acrid	Black ash, easily crushed

2. Budget Saving Recipes, Quaker Oats Company.

3. Cereals and Pasta in Family Meals, G-150, USDA.

EVALUATION

Ask aides to demonstrate how they will use this information in teaching situations.

IDEAS FOR SUPPLEMENTAL LESSONS

Baking breads with limited equipment.
Preparing cooked cereals for children.

Cost comparisons: baking homemade breads vs. buying breads for a family.

Cost comparisons: serving cooked cereals vs. ready-to-eat cereals.

14565

14566

Lesson 15: HOW TO TAKE A TWENTY-FOUR HOUR DIETARY RECALL

PURPOSE

Trainer agent to help aides:

1. Know the meaning of a 24-hour dietary recall.

2. Understand the purpose of the 24-hour dietary recall.

3. Learn the basic steps in taking 24-hour dietary recall.

4. Develop effective interview techniques which can result in accurate reports.

PRESENTATION

. Discuss the reasons why a 24-hour dietary recall is needed.

-- To identify individual food practices which will later contribute towards providing important information on group food practices.

-- To establish a benchmark for future teaching.

-- To measure progress with families.

Define the 24-hour dietary recall.

-- It is a record of the foods eaten by the person being interviewed during the previous 24 hours. This includes all meals, snacks and beverages and the recall begins with the meal eaten prior to the interview.

14567

Stress need for obtaining first recall as soon as possible after family enters program--before much teaching has been done.

Emphasize need for establishing good communication with family before attempting recall.

Explain the basic steps required to get a 24-hour dietary recall.

-- Aide should ask homemaker to tell what she has eaten during the last 24 hours, starting with the meal before the interview. Answers should be written down in a note pad, not on an official form.

-- All meals, snacks and beverages eaten at home or elsewhere, are to be reported.

-- Example: An aide is getting recall information in the afternoon. She begins by asking, "What did you have to eat and drink at noon today?" Then she asks, "Did you have anything between breakfast and lunch?" Next she finds out what the homemaker ate for breakfast. Then, she asks, "Did you eat or drink anything between the time you ate supper last night and the time you went to bed?" Following this, she asks, "What did you eat and drink for supper last night?" And then she asks what the homemaker had between supper and lunchtime yesterday.

-- Questions such as, "What did you drink with your lunch?" or "What kind of sandwich or soup did you have?" help to provide a complete recall.

-- Questions that suggest answers, such as "Did you have a dark green or yellow vegetable today? should be avoided.

-- When taking the recall, aides should not show, by their expressions or comments, any approval or disapproval of the foods reported.

14568

-- If, for religious or ethnic reasons, a family's food habits are different on holidays or at other times, the 24-hour dietary recall should not be taken at this time.

-- Some factors affecting accuracy of the recall.

Number of times a 24-hour dietary recall has been taken.

People eat differently at different times.

Different interviewers have different effects on people.

Aide's ability to write down what the homemaker tells her--not what she thinks the homemaker means.

Demonstrate and practice 24-hour dietary recall interviews.

-- Trainer agent and aide show other aides the basic technique.

-- Aides practice with each other. Trainer agent should evaluate records obtained.

APPLICATION OF LESSON BY AIDES

Aides understand how to get a 24-hour dietary recall from homemakers and how to apply this information to a teaching situation.

REFERENCES FOR TRAINER AGENT

1. Training Home Economics Program Assistants to Work with Low-Income Families, PA-681, USDA.

2. Instruction Guide For Family Record and Aides List of Families reports.

14569

REFERENCE FOR AIDES

Handbook for Home Economics Program Assistants, PA-680, USDA.

Copy of Aides List of Families report (buff sheet).

Copy of Family Record - Part 2 (buff sheet).

EVALUATION

Trainer agent should compare aides' 24-hour dietary recall with recall information obtained during first lesson. Note changes; discuss with aides in group meeting or individual conferences.

Observe aides' ability to interview other aides. Set up additional practice sessions as needed.

Once the aides are working in the field and 24-hour dietary recall information is being brought in, try to answer questions as they arise. Review basic 24-hour dietary recall techniques with aides when necessary.

14370

Industrial Arts Power Mechanics. Applying Scientific Principles to Power, Energy, and Force.

California State Dept. of Education, Sacramento.
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - 70 145p.

DESCRIPTORS - *STATE CURRICULUM GUIDES; *INDUSTRIAL ARTS; *POWER MECHANICS; *SCIENTIFIC PRINCIPLES; *CURRICULUM DEVELOPMENT; SECONDARY GRADES; PUBLIC SCHOOLS; COURSE CONTENT; TRADE AND INDUSTRIAL EDUCATION; JUNIOR HIGH SCHOOLS

ABSTRACT - This curriculum guide was developed by an NDEA Industrial Arts-Science Curriculum Committee and an NDEA Industrial Arts-Science Editorial Committee during workshops conducted in California and it is designed for instructor use in preparing or revising power mechanics courses in junior or senior high school industrial arts. The material complies with the objectives of the industrial arts programs in California schools, and the content applies the principles relating to power, energy, and force. Sections are: (1) Natural Power, (2) Mechanical Power, (3) Steam Power, (4) Thermal Power, (5) Electrical Power, (6) Hydraulic Power, and (7) Pneumatic Power. Course outlines for power and automotive mechanics, battery terminology, and assignment sheets are appended, and selected references are included. (GEB)

INFORMATION SHEET - PRESSING GARMENTS

Equipment Required

- Ironing board
- Needle, sleeve, and seam boards
- Point presser
- Steam iron and distilled water
- Variety of pressing clothes and hams
- Pressing mitt
- Pounding block or clapper
- Stiff brush
- Machine pressing equipment

Safety Practices

- Follow manufacturer's instructions.
- Avoid flowing garments and large pockets.
- Avoid long hair.
- Turn off machines when not in use.

Precautions

- Use directional pressing to retain garment shape.
- Test fabrics for water spotting.
- Use pressing cloth, iron sleeve, sock, or brown paper to avoid iron shine.
- Avoid making a crease in sleeve.
- Avoid pressing sharp hem line on silks and similar fabrics.

Preliminary Steps

- Remove basting whenever possible before pressing.
- Finish seam edge before pressing.
- Remove pins before pressing.
- Cut darts open on heavy fabrics.

1454

FOREWORD

Courses in industrial arts power mechanics are designed to provide opportunities for students to make applied use of technical information and scientific principles pertaining to power, energy, and force. Students are thus given the types of experiences that will make their knowledge of technical and scientific information meaningful and useful to them and that will cause them to acquire and use proficiently the skills involved in industrial arts power mechanics. These achievements will in turn intensify the students' interest in industrial arts, science, and technology.

Two studies conducted by the California State Department of Education were concerned with the scientific content in automotive/power mechanics courses offered by California high schools. These studies produced information that was used to develop instructional material for the industrial arts area of power mechanics. This information was used by members of the NDEA Industrial Arts-Science Curriculum Committee and the NDEA Industrial Arts-Science Editorial Committee during workshops conducted under the provisions of the National Defense Education Act in the preparation of the material for an experimental edition of *Industrial Arts Power Mechanics.*

A copy of the experimental edition of *Industrial Arts Power Mechanics* and a questionnaire were sent to each automotive/power mechanics teacher in the high schools of California and to selected industrial arts leaders in other states. The educators were asked to review the publication and complete and return the questionnaires. Suggested changes listed in the returned questionnaires were used in revising the material presented in the experimental edition.

The instructional units in this publication provide a sound basis for the preparation of courses of study/instruction in (1) power mechanics per se; (2) power mechanics which serve as introductory courses to industrial arts automotive mechanics, electronics, and metals in grades nine through twelve; and (3) automotive mechanics which make use of the elements of power mechanics.

I am certain that the information presented in *Industrial Arts Power Mechanics* will be of great value in the development of power mechanics courses with the breadth and depth of content that is needed and in which sound, efficient, and effective instructional procedures are emphasized.

Max Rafferty

Superintendent of Public Instruction

NDEA COMMITTEES

NDEA Industrial Arts-Science Curriculum Committee

The specialists in automotive/power mechanics from the ten California colleges with accredited industrial arts teacher-education programs and the teachers, supervisors, and teacher educators who prepared the instructional units for *Industrial Arts Power Mechanics* during a work session held at Fresno State College, December 19-23, 1966, are as follows:

Leslie L. Aldrich, Fresno State College; John C. Davis (retired), Fresno City Unified School District; Raymond E. Fausel, California State College at Los Angeles; Frank J. Irgang, San Diego State College; Richard E. Johnston, Washington High School, Fremont (formerly at Chico State College); Frank H. Jolly, Humboldt State College, Arcata; Mark Jones, Tustin Union High School District; Angus J. MacDonald, San Jose State College; Ted A. McCoy, Hanford High School; Burton A. Pontynen, Pacific Union College, Angwin; Ernest J. Rawson, California State College at Long Beach; James E. Rice, California State Polytechnic College, San Luis Obispo; Frank E. Schroeter, Fresno State College; and Gerald Valente, formerly at San Francisco State College.

NDEA Industrial Arts-Science Editorial Committee

The members of the teams of specialists in science and specialists in industrial arts who, at work sessions in Los Angeles, Sacramento, and San Diego, on December 18-22, 1967, edited and augmented the material for *Industrial Arts Power Mechanics* prepared by the NDEA Industrial Arts-Science Curriculum Committee, are as follows:

O. Bruce Akers, Burbank Unified School District; Ralph C. Bohn, San Jose State College; Joseph E. Freeland, Sacramento City Unified School District; Serafino L. Giuliani, San Diego City Unified School District; Harold L. Marsters, San Diego State College; Richard L. Miller (retired), Los Angeles Unified School District; Jack E. Reynolds, Sacramento City Unified School District; William B. Steinberg, San Diego City Unified School District; and David O. Taxis, Office of the Los Angeles County Superintendent of Schools.

14577

PREFACE

Industrial Arts Power Mechanics presents a set of instructional units derived from the results of two studies, a series of work sessions, and an evaluation of an experimental edition.

Members of the Central California Automotive Technical Committee, who prepared the material for the experimental edition of *Industrial Arts Automotive Mechanics* which was published by the California State Department of Education in 1964, requested the Department to conduct a study to determine the extent to which scientific principles are being applied in present industrial arts automotive/power mechanics courses and the ways in which these principles can be applied to a greater extent in all courses in this area of industrial arts. The Department responded by conducting two studies, one in 1964 and the other in 1965.

The first study was conducted by having teachers of automotive/power mechanics in the high schools of California complete a questionnaire that was designed to secure their reactions to the way in which scientific principles were employed in *Industrial Arts Automotive Mechanics.* All the automotive/power mechanics teachers who responded favored the covering of applicable scientific principles in the automotive publication. The second study was conducted by having teachers of automotive/power mechanics in the high schools of California complete a questionnaire that was designed to report if the teachers applied a given set of scientific principles in their courses and, if so, how. In both studies the teachers indicated a need for curriculum material that would set forth ways of applying scientific principles and provide instructional units covering the broader area of power mechanics.

A series of work sessions for the development of instructional material in industrial arts power mechanics which would apply scientific principles relating to power, energy, and force was financed by funds provided under provisions of Title III of the National Defense Education Act.

The first work session was held at Fresno State College on December 19-23, 1966. Specialists in automotive/power mechanics from the ten colleges in California with accredited industrial arts teacher-education programs were assisted by supervisors and representatives of the Central California Automotive Technical Committee in preparing instructional units in power mechanics. These participants, listed as members of the NDEA Industrial Arts-Science Curriculum Committee in this publication, used the data obtained from the two studies, information presented in the California State Department of Education publications *Industrial Arts and Science* and *Mathematics and Industrial Arts Education,* and science textbooks used in the school systems located near the ten colleges represented at the work session to develop the instructional material.

Additional work sessions were held in Los Angeles, Sacramento, and San Diego on December 18-22, 1967, to augment and edit the power mechanics material developed at the Fresno State College work session. Each work-session team was composed of a specialist in science, a specialist in automotive/power mechanics, and a specialist in industrial arts. The participants in these work sessions are listed as members of the NDEA Industrial Arts-Science Editorial Committee in this publication.

Copies of the experimental edition of *Industrial Arts Power Mechanics* and questionnaires for evaluating the publication were distributed in September, 1968, to automotive/power

614578

mechanics teachers and industrial arts supervisors and teacher educators in California and to selected industrial arts teachers and supervisors in other states. Those who evaluated the experimental edition and responded to the questionnaire became members of the National Power Mechanics Review Committee. Changes suggested by them were taken into consideration in revising the material.

The NDEA project was coordinated by Robert L. Woodward and Norman L. Myers, Consultants in Industrial Arts Education, California State Department of Education.

The education profession in California, and particularly those members working in the area of industrial arts automotive/power mechanics, are greatly indebted to all the teachers, supervisors, and teacher educators who participated in the work sessions and studies which resulted in *Industrial Arts Power Mechanics.*

Industrial Arts Power Mechanics should be of invaluable assistance in the preparation of detailed courses of study/instruction in power mechanics, in the revision of present courses of study/instruction in automotive mechanics, and in the improvement of instruction in California junior high schools and high schools.

CALIFORNIA'S INDUSTRIAL ARTS PROGRAM

The industrial arts program in California schools is an integral part of the total program of education and is designed specifically to help prepare students to meet the requirements of an industrial-technological culture. In this program, which involves study, experimentation, and application, students learn through participation in activities in which they use industrial-technical tools, machines, materials, and processes, as well as English, mathematics, science, and social sciences, in solving meaningful problems.

The four major purposes of industrial arts are to provide opportunity for each student to develop (1) insight and understanding of industry and its place in our society; (2) talent in industrial-technical fields; (3) problem-solving ability related to the materials, processes, and products of industry; and (4) skill in the proficient and safe use of tools and machines. These purposes are furthered by a program in which emphasis is placed on helping students acquire the knowledge and skills basic to many careers.

In kindergarten and grades one through six, the industrial arts program furthers the established educational objectives and enriches the experiences pupils have in attaining such objectives. The industrial arts activities employed for this purpose emphasize planning and construction that is required in meeting needs that arise as the pupils participate in experiences relating to English, mathematics, science, and social sciences. The regular classroom teacher has responsibility for conducting the elementary school industrial arts program.

In grades seven and eight of elementary schools and grades seven, eight, and nine of junior high schools, the industrial arts program is an integral and often required part of the total program of education for all youth. Students are usually guided through a series of introductory experiences in a variety of industrial arts areas. Included in the program are courses which provide instruction in the broad areas of drafting, electricity/electronics, graphic arts, industrial crafts, metals, power mechanics, and woods. In a large school each of these areas of instruction is often taught in a different shop/laboratory; in a small school, several are taught in one shop/laboratory. In each instance the courses are taught by teachers with special preparation in the field of industrial arts and in specially designed and equipped facilities. In these grades emphasis and attention are given to helping students discover and further their aptitudes, abilities, and interests. Provision is made for students to acquire a variety of skills and to profit from participation in creative activities.

In grades nine through twelve and ten through twelve, the industrial arts program provides opportunity for the high school student, regardless of his major, to choose the industrial arts courses he believes will be of the greatest value to him in attaining the goal he is seeking. Included in the program are elective courses which provide instruction in the broad areas of automotive mechanics, drafting, electronics, graphic arts, industrial crafts, metals, photography, plastics, power mechanics, and woods. These courses are taught by teachers with special preparation in the field of industrial arts and in specially designed and equipped facilities. The advanced techniques developed in these courses approach the procedures used in industry. At this level emphasis is given to practices and requirements of occupations and professions relating to each industrial arts area. Challenging opportunities are provided for scientifically and mathematically oriented students to work and experiment with new materials, processes, ideas, and designs.

Knowledge and skills acquired and the experience gained in the industrial arts program assist individuals to select careers wisely and to participate successfully in programs of education and training offered by institutions of higher learning, industry, and government which provide further preparation needed for the chosen careers.

14582

INTRODUCTION

Industrial Arts Power Mechanics is designed to apply scientific principles relating to power, energy, and force. The words *power, energy,* and *force* often have different meanings when used in everyday language than when used in a scientific sense. In a scientific sense these words are defined as follows:

- *Power* is the time rate of doing work.
- *Energy* is the capacity to do work.
- *Force* is a push or a pull.

Industrial arts power mechanics is the study of the generation and conversion of energy to power and the transmission, control, and use of this power. Power mechanics includes the study of (1) the development of power for industrial and home use; (2) the control and measurement of power; (3) the transmission of power through mechanical, fluid, and electrical means; and (4) the use of power to accomplish work.

Each unit in *Industrial Arts Power Mechanics* presents a broad coverage of the topic indicated by its title, covers the scientific principle involved, suggests methods of application of the technical and scientific information, and lists selected references to further technical and scientific information. These references are keyed by numbers in parentheses to the complete list of selected references immediately preceding the appendices. The page numbers listed after each keyed number give further direction for locating pertinent information.

Appendix A of this publication presents a relatively brief course outline for industrial arts power mechanics; Appendix B presents a comprehensive course outline for industrial arts automotive mechanics. The outline on power mechanics is keyed to the instructional units contained in the text and to certain sections of the automotive mechanics outline. Appendix C contains terminology on the storage battery, and Appendix D contains assignment sheets.

One of the purposes of *Industrial Arts Power Mechanics* is to assist in the preparation of courses of study/instruction in (1) power mechanics specifically; (2) power mechanics which serve as introductory courses in other areas of industrial arts; and (3) automotive mechanics which also cover the broader aspects of power mechanics. Another purpose is to demonstrate the interrelationships of the instructional content of industrial arts power mechanics with that of science.

Courses in power mechanics provide an instructional program that is much broader in content than the conventional automotive mechanics courses. In fact, power mechanics employs a selective coverage of many sources of energy and their application.

Knowledge and skills relating to power mechanics may be used in grades seven and eight to augment courses in other areas of industrial arts; however, it is recommended that courses in power mechanics not be provided below grade nine. Introductory courses in power mechanics may be offered in grade nine of junior high schools or four-year high schools. It is recommended that courses in power mechanics be provided at the high school level. Power mechanics may be offered at the high school level as an introduction to courses in the industrial arts areas of automotive mechanics, electronics, and metals.

Today's industrial technology requires knowledge and skills that are not adequately covered in conventional automotive mechanics courses. It is recommended that these conventional courses be more selective in content relating to automotive mechanics and include the broader aspects of power mechanics.

SECTION I
NATURAL POWER

Unit 1 — MUSCLE POWER

The only power available to primitive man was his own muscle. This muscle power made it possible for him to travel, seek food, make simple tools, and fight his enemies. The lever was used by man during this early period. However, relatively great sources of power were available only when the muscles of many men were brought to bear upon a single object. Later, other simple machines were used by man to multiply his muscle power. These were the wheel and pulley, the inclined plane, the wedge, and the screw. (Refer to Unit 6, "Simple and Compound Machines.")

When man learned to domesticate and harness animals, another source of muscle power became available. However, human and animal muscles applied to simple machines limited man's power output. This limitation made it necessary for him to seek other sources of energy. Among the sources of energy to be employed were water and wind, which were used to turn waterwheels and windmills. Today, many sources of energy are used by man. Even though modern man has countless labor-saving devices and makes use of many sources of power, he still depends on muscle power for a great number of daily activities.

It should be understood that simple machines are devices to increase man's strength (muscle). However, such machines cannot increase man's ability to do work, which is defined as the product of the force and the distance through which it moves. Machines merely allow the trade of distance for "quick" force. For example, the wrench used to loosen a nut is a form of lever. If the nut is stuck tightly, it may be necessary to use a longer wrench to increase the leverage. Actually, the work accomplished is not reduced, because the wrench handle is moved a longer distance than the nut moves. The same amount of work has been done, but in a different, more gradual manner. Either speed can be sacrificed to gain force, or force can be sacrificed to gain speed. Because force is required to move the parts of a machine and to overcome friction in the machine, the actual mechanical advantage is never as great as the theoretical mechanical advantage. Thus the efficiency of a machine is always less than 100 percent.

Scientific Principles Involved: Work, Power, Energy, Force

In everyday language the term *work* is used to describe any activity in which muscular or mental effort is exerted. In a scientific sense, however, *work* has a very special meaning: *Work is done*

14584

210

- Trial press on a scrap of fabric or on an inconspicuous area of garment to determine best method.
- Place strip of paper between seam and garment before pressing if fabric will mark through to outside.

Factors and Methods that Control Pressing Results

- Pressure - Lean on iron or use pounding block.
- Heat - Use amount of heat required by the fabric.
- Moisture - Use a steam iron or dry iron with a damp pressing cloth or a wet sponge.

Techniques During Construction

- Place seams together at back of pressed or unpressed pleats.
- Put waistline seams together toward bodice.
- Place yoke seams together away from gathers.
- Put armhole seam together into the sleeve, over the sleeve cap.
- Do not press underarm seam
- Arrange vertical darts and tucks toward the center front or back unless otherwise indicated.
- Place horizontal darts and tucks down unless otherwise indicated.
- Flatten a bulky edge by:
  1. Steaming fabric
  2. Pounding surface flat
  3. Steaming again to set edge
- Place curved area over shaped surface.
- Press each section of garment as it is sewn.

Techniques for Final Pressing

- Follow procedures used during construction.
- Press from outside using pressing cloth if fabric will shine.
- Press plackets closed.
- Remove basting from pleats.

when a force acts on matter and changes its motion or when force moves an object against an opposing force. No matter how long a 50-pound load is held on a person's shoulder, work is not being done in a scientific sense; the upward force that is exerted is merely counteracting the downward force of the load. Work is done in a scientific sense when the load is raised to the shoulder, when it is carried up a flight of stairs, or when it is dragged across the floor. In these cases a force is exerted which moves the object. Expressed in an equation, *work (in foot-pounds) = force (in pounds) × distance (in feet).*

Like the term *work,* the term *power* has a scientific meaning that differs from its everyday meanings. When it is said that a person has great power, it usually means that the person has great strength or wields great authority. In a scientific sense, however, *power is the time rate of doing work.* A man does the same amount of work whether he climbs a flight of stairs in one minute or in one hour, but he does not use the same amount of power.

Matter acquires energy when work is done against gravity in raising matter to an elevated position or when work is done to set matter in motion. The energy thus acquired can be used to do work. In mechanics there are two kinds of energy, kinetic energy and potential energy. *Kinetic energy is energy due to motion of a mass.* A moving automobile, a bullet leaving the muzzle of a gun, a spinning flywheel, a rolling ball, and falling or running water all possess kinetic energy. *Potential energy is stored energy.* The water impounded behind a dam has potential energy. This energy becomes kinetic when it is used to turn a waterwheel or turbine. The coiled mainspring of a watch has potential energy because work was done in winding it. Its potential energy becomes kinetic as the spring unwinds.

Force is directly related to work and energy. *Force is a push or a pull.* However, forces do not always push or pull an object. Some combinations of forces just balance each other; as a result, the body on which they act remains stationary. Therefore, force is more completely defined as that which produces or prevents motion or has a tendency to do so.

Application of Principles

1. A bicycle dynamometer can be made to illustrate the use of muscle power to produce electric power. The bicycle is held upright by a front-wheel block and balancing supports on each side of the rear-wheel axle. Two rollers (approximately four inches in diameter) are placed under the rear wheel of the bicycle. The front roller is the idler, and the rear roller is the driver. A pulley wheel is attached to the driver roller. A belt from this pulley wheel is placed around the pulley wheel of an automobile alternator with a variable field control. (The pulley selected should permit about 1,000 revolutions per minute.) All supports of parts should be attached to a plywood base/floor. The generated current is fed to a 12-volt storage battery for stabilizing voltage. A bank of lights or other electrical load can be employed to use up the electricity produced by the alternator. Meter readings can be made and horsepower computed.
2. Simple machines among the tools and machines in a facility can be identified and demonstrated by students. (Refer to Unit 6, "Simple and Compound Machines.")

Unit 2 — WATERWHEELS

The waterwheel, sometimes called a gravity wheel, is a simple mechanical device to convert water power to mechanical power (rotary motion) against a resistance at the axle of the wheel. The three general types of waterwheels are the undershot wheel, the overshot wheel, and the breast wheel. The undershot wheel was one of the first engines designed to do work. It was introduced over 2,000 years ago by the Egyptians and the Persians. Undershot waterwheels are made so that

24585

when the paddles at the bottom of the wheel are dipped into a stream or river, the current of water exerts a force against the paddles and turns the wheel. Overshot wheels make use of water that is directed at the top of the wheel on the downward side. Breast waterwheels, which are similar to the undershot wheels, are rotated by directing water above the center of the wheel on the downward side. The early waterwheels were constructed of wood; iron parts became common during the Renaissance.

With the introduction of hydraulic turbines in the early part of the nineteenth century, the importance of waterwheels decreased. Today, they are limited to small power plants.

The modern water turbine has a wheel or rotor with a series of blades or vanes. Instead of being placed in an open stream or river, these rotors are enclosed in a housing. Water under pressure is directed to them through pipes and nozzles. Usually, the pressure of the water is built up by damming a water source.

Scientific Principle Involved: Water Pressure

At sea level the pressure of air from all directions is 14.7 pounds per square inch (psi). Water also has pressure. For about every 34 feet below the surface of water, the pressure is multiplied by 14.7 pounds per square inch (the amount of pressure at the surface). The pressure of deep water must be taken into consideration when designing huge dams. The thickness of the base and the strength of the concrete must be such that they will withstand the pressure of the water held back. It is this water pressure that turns the rotors of the water turbines found in the electrical power plants located at the base of dams.

The force of the water strikes against the paddles at the bottom of the undershot waterwheel (left) and at the top on the downward side of the overshot waterwheel (right).

Application of Principle

1. A model waterwheel can be constructed. Water conducted by a tube from a faucet can be directed on the blades of the waterwheel to demonstrate the three types of wheels: undershot, overshot, and breast.
2. The pressure of water can be demonstrated by pouring two quarts of water into a cellophane bag. If the bag is lifted and four holes are punched vertically (near the bottom, about an inch apart) on two sides of the bag, the water will spurt farthest from the holes nearest the bottom of the bag.

Selected References

Note: The numbers in parentheses in this section refer to entries in the list of selected references that appear within this publication immediately after the text.

The U.S. Navy's hydrofoil gunboat is powered by water jet and is capable of speeds in excess of 40 knots. Water is drawn through rear struts into centrifugal pump and is then jetted through nozzles near the stern (Boeing Company, Seattle, Washington).

14586

Unit 3 — WINDMILLS

Windmills consist of a rotating element or wheel driven by the wind that causes the turning of a shaft connected to equipment to perform useful work. Windmills are practical when intermittent power is required, as in pumping water to storage tanks and generating electrical power for charging storage batteries in power-supply systems.

The windmill was one of the earliest devices used to obtain power from natural sources. Some records indicate that windmills were in existence prior to the seventh century. The windmill was in use in Persia during the tenth century and in Western Europe near the close of the twelfth century.

During the sixteenth century the general form of the Dutch windmill was stabilized. No essential changes were made until the start of the twentieth century, when research showed the way for significant improvements in the form of sails or windmill arms. Modern windmills have tended toward high-speed designs or types possessing wheels rotating at a large number of revolutions per minute for maximum efficiency in operation.

Present types of windmills are the multivane, the propeller, and the S rotor. The multivaned wheel, though the least efficient of the modern windmills, has the most numerous applications in the United States. The multivaned and propeller windmills possess rotors that revolve about a horizontal shaft, and hence it is necessary to orient the rotors into the wind through the use of a vertical vane or rudder. Since the S-rotor type of wheel is mounted on a vertical shaft, it is possible to take advantage of the current of wind without swinging the entire unit on a vertical axis.

Scientific Principle Involved: Horsepower Output of Windmill

The available power in a current of wind is due to the kinetic energy of the mass of air flowing through a given area per unit of time. In a windmill the area concerned is the frontal area swept out by the rotating element. At sea-level conditions of air pressure and temperature, the available horsepower per unit of area is given by the equation $Hp = 0.00000214 \times V^3$, where V is the wind velocity in feet per second. This equation gives the results of horsepower output of a windmill (area 100 square feet, efficiency 30 percent) as follows:

Wind speed in feet per second	10	20	30	40	50	100
Wind speed in miles per hour	6.8	13.6	20.4	27.2	34.0	68.0
Windmill horsepower ..	0.06	0.5	1.7	4.1	8.0	64.0

Application of Principle

1. A windmill can be constructed for demonstration and use in generating electrical power for charging storage batteries.
2. A cup-type anemometer can be used or constructed to check wind speed.

Unit 4 — HEAT COLLECTORS

It is safe to assume that the earth's supply of fossil fuels will last for at least one and one-half centuries and that the supply of uranium will last for a century beyond the fossil fuels. However, these fuels are lmited, and energy sources which are not presently being used must be put to efficient use in the future.

The energy of the sun is the most obvious source of energy. The daily supply is tremendous. In two days the sun provides the United States with energy equal to all our remaining fossil fuel reserves. Much of this energy is lost, however, because of clouds and other forms of energy dispersion. Yet the energy reaching the earth is still far greater than our needs. If only 1 percent of available ground area were used for solar power plants, these plants would have a theoretical capability to produce more power than all the steam and hydroelectric power plants in the world.

There are two major problems in making practical use of solar energy – collecting it and using it at low intensity. Heat energy at normal earth temperatures is difficult to put to practical use. More research and study are needed before solar energy becomes a major source of controlled power.

14587

Some current uses, though small, are noteworthy. They are as follows:

1. Solar cells convert solar energy to electricity. Even though the output is low, solar cells are used to power satellites and provide power for remote telephone boosters.
2. Solar evaporation of seawater has been a major source of salt and other ocean minerals for centuries. Also, the evaporation and condensation of seawater as a source of fresh water have been effective in small and experimental installations.
3. Solar cooking units have been designed and manufactured for use in areas having a substantial amount of available sunshine.
4. Solar heating of homes has been successful in regions where there is an abundance of sunshine.

A solar cell is composed of a wafer of silicon-arsenic coated with boron.

Scientific Principle Involved: Heat

The temperature of a body is the measure of the motion of its molecules. Molecules of all substances possess kinetic energy, which may be expressed by the formula $KE = 1/2MV^2$ where KE is kinetic energy, M is mass, and V is velocity. As the temperature of a substance rises, the kinetic energy and, therefore, the velocity of the motion of its molecules increases.

Heat is transferred by conduction, by convection, or by radiation:

1. *Conduction:* Through motion, kinetic energy is transferred from one atom or molecule to other atoms or molecules adjacent to it. In this way heat travels through a body by conduction. Metals are good heat conductors; nonmetallic substances are poor conductors.
2. *Convection:* The increased molecular motion, due to a rise in temperature, causes substances to expand, thereby reducing their density. When any portion of a gas or liquid is heated to a higher temperature than the remaining fluid, it becomes lighter and floats upward. The resulting movement is a convection current. Heat is distributed in gases and liquids by these convection currents.
3. *Radiation:* Heat in the form of radiant energy travels in straight lines through space and transparent materials. Radio waves, infrared light, visible light, ultraviolet light, and x-rays are all forms of radiant energy. When radiant energy, particularly that of the infrared portion of the spectrum, strikes an opaque object, some of it is reflected back into space and some is absorbed. The absorbed portion increases the kinetic energy of the atoms or molecules that make up the substance, thus increasing its temperature.

All opaque bodies radiate some heat, depending on their temperature, and all such bodies absorb some of the radiant energy that strikes them. The amount of absorption or radiation depends mainly on the surface and color of the body. Rough, dark-colored surfaces absorb and radiate more heat. Smooth, light-colored surfaces absorb and radiate less heat.

Solar cooking can be demonstrated by using a concave mirror or bright metallic surface to convert the sun's rays to heat for power.

14588

Application of Principle

1. A simple heat collector can be made from a box which is painted a dark color, preferably black. A second collector box, painted white, should also be made. A thermometer should be placed in each box and the boxes placed in bright sunlight. The temperature readings of each thermometer should be recorded at periodic intervals. An appropriate graph can be plotted.

2. Solar cooking can be demonstrated by using a concave mirror or bright metallic surface. A match or small pieces of wood can be ignited at the focal point of the mirror or reflector. A larger unit, designed to roast hot dogs or cook other foods, can be built with a bright, concave, metallic surface as a reflector. Care should be exercised since very high temperatures are possible.

3. The conversion of solar energy to electricity can be illustrated through the use of solar cells. A solar motor assembly can be built which consists of a pair of solar cells wired to a small motor. The motor will operate whenever the cells are exposed to sunlight.

Unit 5 — SOLAR STILLS

The available supply of fresh water may soon be inadequate for many cities and countries in the world. Many islands, such as the Virgin Islands, have inadequate supplies of fresh water for drinking and for irrigating crops. As a result, considerable effort has been expended to extract ocean water that can be used as fresh drinking water.

One method, often recommended for survivors at sea, involves the evaporation and condensation of seawater. During evaporation the water goes into the air in the container, leaving the salt and other minerals behind. When the water is condensed, it is fresh and free of salt and other minerals.

This method, known as the solar still method, is inexpensive but impractical for large quantities of water. It is currently used as an emergency or low-production method of desalting seawater. Future improvements might find it or a modification of the system more practical to meet the growing demand for fresh water.

Scientific Principle Involved: Distillation of Water

Seawater is not satisfactory for drinking because of its high saline content. Distillation or evaporation has long been used as a method to obtain pure water. The process consists of evaporating or boiling water to form water vapor or steam, which is then condensed to liquid again. The condensation takes place on any surface which is cooler than the water vapor or steam. All suspended matter and any dissolved material which has a higher boiling point than water are left behind.

Application of Principle

A solar still may be developed through the use of a large, clear plastic bag, a black towel, or other dark, absorbent material, and a collector tray. The plastic bag should be rigged as a canopy over the black towel. The towel should be soaked in salt water. When the unit is placed in the sun, the solar energy will be absorbed by the towel and the water will be heated and evaporated. The water vapor will rise to the inside of the canopy. Since the air is cooler within the canopy than at the towel, the water will condense on the inner surface of the clear plastic bag. A collector tray along the edge of the canopy should be used to collect the small quantities of condensed fresh water.

SECTION II
MECHANICAL POWER

Unit 6 — SIMPLE AND COMPOUND MACHINES

Machines are used to transform energy, transfer energy, multiply force, multiply speed, and change the direction of a force. A generator transforms mechanical energy into electrical energy. A steam or gas turbine transforms heat energy into mechanical energy. Machines are used to transfer energy from one place to another; for example, in an automobile the connecting rods, crankshaft, drive shaft, and rear axle transfer energy from the combustion in the cylinders to the rear wheels. Machines are used to multiply force; thus, an engine can be lifted out of an automobile by using a system of pulleys. The pulley system makes it possible to raise the engine by exerting a force which is smaller than the weight of the engine. However, this smaller force must be exerted over a greater distance than the height through which the engine is raised, and the engine moves more slowly than the chain which is pulled. A machine, therefore, produces a gain in force, but only at the expense of speed. Machines are also used to multiply speed; for example, a bicycle is used to gain speed, but only by exerting a greater force. No machine can be used to gain both force and speed at the same time. And machines are used to change the direction of a force, as when a single pulley at the top of a flagpole enables one end of the rope to exert an upward force on the flag as a downward force is exerted on the other end.

Mechanical Advantage

When a chain hoist is used to lift a car engine, the chain moves several feet to raise the engine a few inches. When a vise is tightened, the end of the handle is moved (turned) further than the jaw of the vise is moved. When the lever of a paper cutter is pulled down, the hand of the operator moves farther than any point on the cutting edge. In each of these cases and in countless others, a lesser force is exerted to gain a greater force at the expense of having to exert the lesser force over a longer distance. Each of these machines provides mechanical advantage.

Scientific Principle Involved

By the use of simple or compound machines, a person is able to multiply the force that his muscles are capable of exerting. When a 20-pound force is exerted through a pulley arrangement of a chain hoist to lift a 200-pound engine, the effort of a person is multiplied ten times. Mechanical advantage equals weight supported *(W)* divided by the force applied *(F)* in any mechanical device; or, to put it another way, mechanical advantage equals

PB214590

W/F. The mechanical advantage then is ten. With the vise the mechanical-advantage principle is the same except that it is achieved by a combination of two simple machines, the wheel and axle and the screw or inclined plane. Likewise, the paper cutter combines the lever and the wedge.

The mechanical advantage of force of a machine is termed theoretical or actual. Theoretical mechanical advantage is the ratio of the distance the effort force moves to the distance the resistance force moves. Actual mechanical advantage is the ratio of the resistance force to the effort force. The efficiency of any machine is the ratio of its actual mechanical advantage to its theoretical mechanical advantage converted to a percent.

Simple Machines

There are six simple machines. These are the lever, the pulley, the wheel and axle, the inclined plane, the screw, and the wedge. Other machines are either modifications of one of these simple machines or a combination of two or more of them. The pulley and the wheel and axle are fundamentally levers, while the wedge and screw are modified inclined planes. Many complicated machines are combinations of simple machines. A combination of two or more simple machines is called a compound machine. A drill press is an example of a compound machine. Many of the simple machines are found in the drill press.

Lever

The lever was one of the first simple machines known to man. In making use of leverage, he found that the turning effort exerted depended on (1) the amount of force applied; and (2) the length of the lever arm. The same form of simple lever is still used to move heavy objects. In modern machines many other more complex forms of this simple machine are used in gaining mechanical advantage or speed of movement. Some examples of tools (machines) that use the lever principle are tire jacks, scissors, hammers, bolt cutters, pliers, tin snips, crowbars, vise handles, wrenches, hand-lever punches, paper cutters, drill presses (feed handles), and squaring shears (treadles). Pushing, pulling, raising, or lowering of handles on most tools are applications of the principle of the lever. Moving the accelerator, clutch, brake pedals, turn-indicator levers, and manual gearshift levers are examples of the application of the lever in automobiles. Operating cranks and kick starters are examples of the application of the lever principle found in other units driven by internal-combustion engines. In most instances the lever is used to increase force.

Scientific principle involved. A lever is a rigid bar that is free to turn about a fixed point called the fulcrum or pivot point. A force applied to one point on the lever may be used to overcome resistant force at another point on the lever. The ratio of the force applied to the resistance that is overcome is called the mechanical advantage of the lever. The theoretical mechanical advantage of a lever may be found by dividing the distance from the effort (force) to the fulcrum by the distance from the resistance (load) to the fulcrum. Levers are of three classes. First-class levers have the fulcrum between the forces; some examples include tin snips, pliers, and scissors. Second-class levers have the load or resistance between the effort and the fulcrum; paper cutters and welding tank trucks are examples. Third-class levers have the effort applied between the fulcrum and the resistance; examples are calipers and tweezers. These tools are familiar examples of the use of levers. Levers may be used to increase force, distance, or speed. If the resistance force is greater than the effort force, then the effort force must

A first-class lever (top) has the fulcrum between the effort applied and the load (e.g., prying with a crowbar); a second-class lever (center) has the load between the effort applied and the fulcrum (e.g., moving a wheelbarrow); and a third-class lever (bottom) has the effort applied between the fulcrum and the load (e.g., using a broom).

0C14591

move through a greater distance (faster) than the resistance. The work done by the lever can, therefore, never be greater than the amount of work produced by the effort on the lever. If the work done by the lever were greater than that put in, the lever would be an energy-creating or perpetual-motion machine.

Wheel and Axle

The wheel serves a number of purposes. Like a fixed pulley, a road wheel on an automobile supports a load and permits it to move in a direction parallel to the road surface. When power from the engine causes the rear axle to turn, the rear wheels act as levers to move the load they support. The wheels also function as levers when the brakes are applied. Gears, sprockets, pulleys, windlasses, and winches are examples of the wheel and axle.

Scientific principle involved. When in motion, the wheel is a continuously rotating lever. The center of the wheel is the fulcrum. A wheel that, like a front wheel on a car, merely rolls and supports a load has a mechanical advantage of one. Drive wheels on powered vehicles usually have a mechanical advantage of less than one. And wheels with brakes have a similar mechanical advantage. The amount of mechanical advantage depends on the wheel radius, rear axle ring-gear radius, brake drum, or disk radius. A cable or rope windlass is a wheel and axle with a mechanical advantage greater than one. The amount of mechanical advantage gained by a windlass depends on the diameter of the drum and the length of the driving handle.

Inclined Plane

The inclined plane is a great help to workmen because of the mechanical advantage it provides. Oil drums and other heavy objects can be raised or lowered by means of an incline. The same principle is involved in the grading of roads and mountain trails and in the ascent and descent of winged aircraft in flight.

Scientific principle involved. An inclined plane consists of a plane surface with one end or side higher than a plane parallel to the earth's surface. Mechanical advantage is gained when an object is moved up a slanted surface rather than when it is lifted vertically. As an example, a 300-pound drum can be rolled up a 12-foot incline that rises 4 feet at one end by a calculated force of 100 pounds.

Wedge

Man has found many applications of the principle of the wedge. The great force that can be exerted by this simple machine makes it useful in (1) separating or forcing one thing away from another (by the use of axes, chisels, knives, splitting wedges, and wedges used to lift heavy objects); and (2) locking or holding objects together (by the use of wedges in hammer handles; pegs, nails, and other fasteners that are driven into materials; corks in bottles; and gears or wheels that are pressed on the ends of shafts).

Scientific principle involved. The wedge is an object that has a greater cross section at one end than at the other. As a wedge is moved in the direction of its smaller cross section, a greater force is exerted at right angles to this motion by its sides. The wedge is a form of the inclined plane, and its mechanical advantage is gained in the same manner. If a wedge has a length of 6 inches and its cross section increases from zero to 2 inches, it will have a calculated mechanical advantage of three.

Pulley

Pulleys and belts, as well as sprockets and chains, are used in driving all types of equipment. The drill press, lathe (wood and metal), jig saw, milling machine, chain hoist, block and tackle, and many other devices would be rendered useless without the simple machine known as the pulley. The pulley provides a means of transmitting mechanical power from a single driving source to one or more driven mechanisms. The pulley, as used with a chain hoist, provides a mechanical advantage; it makes easier the lifting of a heavy object, such as an automobile engine. Pulley and belt combinations, as found in the drill press, are used for obtaining desired speeds. Pulleys and belts are used to transmit power from internal-combustion engines to drive electric generators and fans of vehicles and stationary units.

Scientific principle involved. A pulley, which is a wheel that turns readily on an axle, provides a means of transferring power through a belt or chain from one location to another. With this transfer of power, it is possible to accomplish work at a location removed from the source of power. In the lifting or moving of an object, a single fixed pulley merely changes the direction of force. In a pulley system with one movable pulley, the force moves twice as fast as the load. A combination of

14592

pulleys of varying sizes may be used to increase or decrease speeds beyond the speed of the driving source. The law governing this principle is that the ratio of the speeds at which the pulleys turn is inversely proportional to the diameters of the pulleys. As an example, an 8-inch pulley at the driving source will make one revolution for every two revolutions of a 4-inch driven pulley.

Screw

Certain devices are regulated with adjusting screws. As adjusting screws are turned, force is applied to control the space between the parts or to provide the resistance that may regulate the flow of gas, liquids, or electricity. The correct setting is determined by the amount the adjusting screw is turned and, in some cases, can be checked with an electronic instrument or a pressure gauge. A few devices that use adjusting screws are oxyacetylene regulators, padding capacitors, paint-spray guns, automobile carburetors, micrometers, and compasses. Clamps and vises make use of the simple machine known as the screw. A common clamping operation is holding material firmly in a drill-press vise while the stock is being drilled. The handle of the vise acts as a lever, multiplying the mechanical advantage of the screw. The total mechanical advantage of such a device is the product of the mechanical advantages of the two simple machines.

Scientific principle involved. A machine screw is a cylindrical body with a helical (spiral) groove cut into its surface. For practical purposes a screw may be considered an inclined plane in the form of a helix. The screw must resist tension (strain) and shearing (cutting). In its application as a simple machine, the screw is machined to precision accuracy in both fit (correct size) and pitch (distance between threads). The fit of the screw determines how much friction will take place as the screw is turned. With too much friction, the screw is difficult to adjust; with too little friction, the screw is difficult to keep adjusted. The pitch of the screw thread determines how finely a particular instrument can be adjusted. If the fit and the pitch are not correct, the effectiveness of the adjusting screw is decreased.

Compound Machines

An engineer designing a steering system for an automobile must devise a set of levers and gears that provides enough mechanical advantage to turn the front wheels easily yet requires a minimum number of turns of the steering wheel for the convenience of the operator. Consideration must be given to the diameter of the steering wheel, which is rigidly attached to the steering shaft; to the ratio of the gears in the steering gear box; and to the length of the levers, which move the wheels at their pivot points. Power assistance (power steering) is often built into an automobile to assist the driver in exerting greater force in turning the wheels.

Scientific Principle Involved

The function of a machine is to convert energy to useful work. The steering system of an automobile is a machine that enables a person to multiply the force produced by his muscles. The lever is a rigid bar that is free to turn about a fixed point. The arm or end to which force is applied is the effort arm; the arm that moves the load is the resistance arm. The mechanical advantage, which depends on the lengths of the two arms, may be increased by lengthening the effort arm or shortening the resistance arm. The gear is a form of lever. It is a series of levers around a circle used to transmit continuous force to another gear. One gear of a pair may be the resistance arm and the other the effort arm. The wheel rigidly attached to an axle is also a form of lever. The rim of the wheel is like a series of levers and is more convenient to use than a single lever. A combination of two or more simple machines, such as the lever, gears, and wheel with axle, is a compound machine. In almost all cases the total mechanical advantage of a compound machine is the product of the mechanical advantages of the simple machines of which it is composed.

Application of Principles

Examples of simple and compound machines can be identified among the hand tools and components of machines in the facility as well as in the systems of internal-combustion engine units. Simple and compound machines can be demonstrated by using (1) a yard or meter stick as a lever to lift weights; (2) weights, levers, and spring scales to show mechanical advantage and torque; (3) brake pedals on automobiles to illustrate classes of levers by disconnecting the brake pedal from the master cylinder and connecting a spring scale or torque wrench to the pedal; (4) a spring scale

14593

connected to the rim of a steering wheel to measure the force necessary to steer the vehicle; (5) input and output transmission shafts to determine gear ratios; (6) the rolling of a grease drum up a ramp to demonstrate the inclined plane; and (7) a wood or metal wedge to secure tool heads.

Unit 7 — LUBRICATION

For the proper lubrication of a four-cycle internal-combustion engine, the oil used must prevent rotating and sliding metal surfaces from coming into contact while under heavy shock loads and widely varying temperatures. Internal liquid resistance to flow prevents oil from being squeezed from between moving metal surfaces of bearings, cylinder walls, and valve trains. This property of oil is commonly referred to as viscosity.

Viscosity of Oils

Viscosity of oils must be discussed in terms of (1) body, or the resistance of the oil film to puncture; and (2) fluidity, or the ease with which oil flows through distribution lines and coats metal surfaces. These characteristics can be considered opposites since the more fluidity an oil shows, the less body it has. Modern engines require an oil with great fluidity because of close tolerance but with body resistive to breakdown under the heavy loads and temperatures imposed by high horsepower output.

The viscosity of an oil can be determined by a device called a viscosimeter. The viscosimeter determines the time it takes a measured quantity of oil at a certain temperature to flow through a metered orifice.

Temperature affects oils by increasing their viscosity as the temperature drops and decreasing their viscosity as the temperature rises. According to the viscosity rating system of the Society of American Engineers (SAE), lower numbers indicate a thinner oil, higher numbers a thicker oil. Winter grade oils have a *W* after the SAE number to indicate that the oil was tested at zero degrees F. and 210 degrees F. The three automotive winter grades are SAE5W, SAE10W, and SAE20W. Automotive oil not tested at zero degrees F. is rated as SAE20, SAE30, SAE40, or SAE50. Oils can have multiple ratings, such as SAE10W-30. This number means that the oil can be substituted for grades SAE10W, SAE20W, and SAE30.

The American Petroleum Institute (API) has devised a system for classifying motor oils according to *engine service requirements.* This classification system provides six service ratings, three for gasoline engines and three for diesel engines. The first letter in each designation indicates the type of engine: *M* for the gasoline and LPG engine, and *D* for the diesel engine. The second letter in each designation indicates the type of service. The three service ratings for gasoline or spark-ignition engines are (1) *MS* for severe service; (2) *MM* for medium service; and (3) *ML* for light service.

A Viscosity Index (VI) evaluates oil in terms of viscosity change caused by variations in temperature. The adopted VI rating scale goes as high as 300. The higher the VI number indicated, the less the oil viscosity varies with temperature. In a very cold climate, the viscosity index is very important. It may be necessary, for example, to start an engine at below zero degrees F., but in a few minutes have oil temperature within the engine at 200 degrees F. In this situation the oil must not be so thick at starting that it prevents cranking, but not so thin at operating temperature that engine damage results.

Oil companies blend oil with additives to give the proper viscosity index for the type of service for which the oil is intended. Multiviscosity oils, in wide use now, are premium oils that have a high VI rating. The viscosity of an oil used in an automobile engine has much to do with the life of that engine. Manufacturers' recommendations should be followed carefully in selecting and using oil.

With the development of improved lubricating oils and more efficient oil and air filters, automotive manufacturers have liberalized their recommendations for oil changes. When favorable operating conditions exist, some manufacturers recommend that oil should be changed every two months or after 4,000 miles of operation, which-

14594

Suggestions for Specific Types of Fabrics

- Use needle board for pressing pile fabrics.
- Use only warm iron on man-made fibers and silk.
- Press fabrics with a raised design face down on softly padded board.
- Press lace from wrong side on ironing board covered with terry cloth.
- Set iron for the fabric on the side which is being pressed when using a bonded fabric.
- Leave wool fabrics on board until dry to avoid stretching.
- Use dry iron on all sheer fabrics except cotton.
- Do not press synthetic fur or vinyl fabrics.

Solutions to Pressing Problems

- Use stiff brush when nap becomes flattened.
- Remove shine by pressing over with a very damp cloth.
- Remove scorching by sponging with hydrogen peroxide to which sodium perborate has been added (1 teaspoon per pint). Rinse well. Test on colored fabric first in an inconspicuous place.
- Reshape curved area by pressing with steam over shaped surface.
- Use steam machine or steam iron to revive flattened pile surfaces.

1456

ever occurs first. Other manufacturers favor an oil change every two months or after 6,000 miles, whichever occurs first. All recommend that for more adverse driving conditions, such as start-and-stop driving, cold-weather driving, or driving through dusty areas, the oil should be changed more frequently.

Scientific Principle Involved:
Fluid Friction and Viscosity

When a liquid (fluid) is set in motion, internal structures (molecules) move at different velocities. Friction is involved as these structures slide over or rotate around each other. This friction is known as viscosity.

A liquid is made up of molecules in motion which are of different sizes for different liquids. Liquids with large molecules tend to have a higher viscosity than liquids with small molecules. This phenomenon might be explained by comparing the larger molecules to rocks and the smaller molecules to fine sand. It is much easier to force a pile of sand to flow than a pile of rocks because rocks tend to pile up and resist motion. Liquids with different-sized molecules can be mixed to obtain a desired viscosity. The smaller molecules can be thought of as little bearings that fit in with the larger molecules to provide a "ball-bearing" effect to reduce the resistance to flow of the larger molecules.

The molecular structure of a liquid is always in motion; how active the molecules are is determined by temperature. The lower the temperature, the slower and closer together are the molecules. The higher the temperature, the more rapidly and farther apart the molecules move. The more activity displayed by the molecules, the less is the energy that will be necessary to cause the liquid to flow. The opposite is true for lower temperatures. If the temperature is raised too high, the molecules tend to get so far apart that, for all practical purposes, the viscosity of the liquid may disappear.

Application of Principle

1. Obtain several different SAE grades of oil. Provide a funnel with a small metering orifice. Heat measured quantities to a given temperature (such as 200 degrees F.) and time the flow through the funnel. Cool the same samples in dry ice or in a refrigerator to a given temperature (such as 32 degrees F.). Compare the rates of flow.
2. Show the effect of cold on the cranking of an engine by cooling a small gasoline engine with dry ice. Compare how difficult this engine is to start with different grades of engine oil in the crankcase.
3. Compare the viscosity of various oils by a simple device. Place oils to be tested in plugged test tubes, each of which contains a small steel ball. Place the test tubes in a rack so that all can be rotated at the same time. The more viscosity an oil has, the longer will it take for the oil to reverse in the test tubes and for the steel ball to settle to the bottom.

Selected References

Note: The numbers in parentheses in this section refer to entries in the list of selected references that appear within this publication immediately after the text.

(4), p. 37; *(20)*, pp. 260-90; *(21)*, pp. 338-45; *(22)*, pp. 174-75; *(27)*, pp. 225-26; *(66)*, pp. 39-43; *(69)*, Chapter 5, p. 5; *(75)*, Chapter 10, pp. 1-2.

Functions of Lubricating Oil

Lubricants are used to slow down wear and to reduce friction between two moving surfaces. The lubricating oil used in the four-cycle internal-combustion engine performs at least seven functions. It (1) lubricates moving parts to reduce wear; (2) reduces friction and power loss; (3) prevents spot overheating by absorbing heat as it circulates; (4) seals piston rings, pistons, and cylinder walls to prevent loss of gases on the power stroke; (5) absorbs shock in bearings; (6) dissolves lacquerlike substances and suspends other by-products of broken-down oil and worn metal through the use of detergents and the oil-filter action (helps keep engine clean); and (7) neutralizes acids (formed in the breakdown of oil by heat which would damage metal parts) through the use of additives.

Cylinder walls, pistons, and piston rings are exposed to the high heat of the burning fuel-air mixture (particularly on the power stroke). This heat will evaporate some of the oil coating on pistons and cylinder walls. The oxygen from the unused air in the fuel-air mixture together with the high temperature will partially burn part of the oil coating the exposed surfaces, leaving carbon. The heat also "cracks" some of the oil molecules, causing the formation of additional carbon.

Lubrication of the two-cycle engine is quite different from the lubrication of the four-cycle engine. Since the fuel mixture must travel through

14595
ECFF

the crankcase, a reservoir of oil cannot be stored there. The lubricating oil is mixed with the gasoline and is then put into the gas tank. (Two-cycle engine manufacturers are now developing and marketing engines with oil-metering devices that eliminate the need for premixing the oil and gasoline.) The lubricating oil for all crankcase parts enters the crankcase as part of the fuel mixture. Millions of tiny oil droplets suspended in the mixture of gasoline and air settle on the moving parts in the crankcase, providing lubrication.

Scientific Principle Involved:
Effect of Heat on Hydrocarbon Molecules

Heat is one form of energy and has the capacity of doing work (both useful and destructive). High temperature is used in petroleum refineries to break large hydrocarbon molecules into smaller ones (cracking) in order to obtain more gasoline. The carbon and hydrogen atoms of the hydrocarbon molecules are held together by chemical bonds. When heat is added and the temperature is thereby raised, the atoms begin to vibrate, stretching the bonds (very much like bouncing a ball tied to a rubber band). When the vibration becomes too violent, the bonds begin to break.

Application of Principle

1. Demonstrate the effect of heat on lubricating oil by dipping one end of a 1-foot welding rod in oil, holding the rod with pliers, and heating the opposite end with a torch. The heat travels along the rod, and the oil begins to smoke (evaporate). Continued heating produces a black, sticky coating on the rod from the oil (carbon and lacquerlike substances). Test and compare various brands and viscosities of oils. Also test used oils (crankcase drainings).
2. Check the acid content of used oil by placing a small quantity of crankcase drainings on a piece of metal.

Dry, Greasy, and Viscous Friction

Friction is a force which resists motion and converts the energy of motion into heat. The "drag" due to friction depends on the roughness of the surfaces in contact, the amount of surface, and the force holding them together. Friction is both a help and a hindrance in the operation of an automobile. It helps a person to hold and turn the steering wheel. Without friction the brakes would not work and the tires would not have traction. The steering wheel, brakes, and the tire tread are all designed to increase the effectiveness of this helpful friction.

However, friction in the automobile engine and along the power train wastes energy and causes wear. The use of machined and polished moving parts, bearings, and proper lubrication all help to decrease the amount of friction. They enable the engine (and power train) parts to last longer and the automobile to perform more efficiently.

There are three types of friction: dry, greasy, and viscous. Dry friction occurs when two dry surfaces rub together. The friction between the brake lining and the brake drum is one example of dry friction. Greasy friction occurs when a small quantity of oil or grease is applied between the two contacting surfaces. Grease is applied to automobile door latches and the front wheel suspension system. Viscous friction occurs between the layers of a liquid. The lubricating oil in an automobile engine is forced between the moving metal surfaces. Viscous friction is thus substituted for sliding friction.

Scientific Principle Involved:
Dry, Greasy, and Viscous Friction

Atoms and molecules make up solids, liquids, and gases. They all behave as though they were very tiny balls. The surfaces of highly polished solids appear to be perfectly smooth. However, photographs of these surfaces, taken with an electron microscope, show "hills and valleys." The "hills" of one contacting solid surface tend to fit into the "valleys" of the other, causing friction (resistance to movement) between solid surfaces. The molecules of greases are larger and move about more slowly than those of oils (at the same temperature). The constant movement of the molecules prevents the formation of permanent "hills and valleys" between layers of greases and oils. Friction in both oils and greases should be, and is, less than solid friction, and oil (viscous) friction is less than greasy friction.

ED 044596

Application of Principle

1. Measure relative friction by using several blocks of the same size (but of different materials), a spring balance, a long, flat surface, grease, and lubricating oil. Tie a string to each block in order to attach the spring balance. Test each block for all three types of friction (dry, greasy, viscous). Place a block on the long, flat surface with the spring balance attached to the block. Pull the spring balance steadily until the block begins to move. Read and record this "starting force" (pull). (The difference between the starting and moving force is the friction.) Test the blocks for dry friction and record the date of testing in a table. Coat each block with grease and repeat the experiment. Observe and record the starting force and the moving force for each block. Cover the long, flat surface with oil and repeat the experiment. Again observe and record the starting force and moving force for each block.
2. Measure the force needed on the steering wheel of an automobile to turn the front wheels. Place different surfaces under the front tires.

Unit 8 — SPRINGS

Mechanical energy can be stored in a spring and used in many ways in machinery, engines, watches, toys, and other devices. A spring has the capacity to store energy and release it when needed. Springs are made of steel or brass. One of the most frequent uses of springs is to supply motive power in a mechanism. A good example of this is found in the windup toy. When the toy has been wound up and the lever has been activated, the toy moves about, releasing the stored energy of the wound spring. The valve springs in an automobile engine are also used to supply motive power or energy. The spring pushes or holds the valve firmly in the valve seat of the engine until the rotating cam mechanism of the engine forces the valve lifter to open the valve. When the lifter stops pushing on the valve, the spring then pushes the valve back into the valve seat.

Another use for a spring is to return displaced mechanisms to their original position. Examples are a door-closing spring or the spring on a cam follower. The coil or leaf spring on the car frame is connected to the axles of an automobile and is used to keep the body at a certain level with respect to the road. As the automobile moves along a highway and irregularities move the car body up and down, the springs help return the body to its original position. These same springs act as shock absorbers on the automobile so that the bouncing effect is absorbed by the springs and is not transmitted to the rider in the car. In modern automobiles hydropneumatic devices are used to limit the speed of the spring action.

Springs are classified according to their shapes. The three main types of springs are the flat or leaf spring, the helical spring, and the spiral spring. The flat or leaf spring, which is made of plates or leaves, has the special advantage of both pushing or

If the pointer attached to the spring returns to the zero mark after the weight is removed, the spring is perfectly elastic.

ec394597

pulling at right angles. The helical spring consists of a wire wound in a helix. It can be used for compression, such as a valve spring, or for tension, such as a brake spring. The spiral spring is a wire or band wound in a spiral that produces a torque, such as the spring found in a recoil device used in a lawnmotor starter.

Scientific Principle Involved: Elasticity

When a force is applied to a solid body, distortion of the body occurs. The greater the force, the greater is the deformation. In an elastic substance the displacement of the atoms and molecules of the substance under stress sets up forces of attraction and repulsion which resist the distorting force and tend to restore the body to its original size and shape. A substance is said to be perfectly elastic if the restoring force, called "elastic recoil," is equal and opposite to the force causing the distortion. If the body does not resume its normal shape and size on removal of the distorting force, its "elastic limit" has been exceeded. Certain metals, such as steel and brass, which possess desirable elastic properties, are used for making springs of various shapes and sizes to withstand the forces of compression, tension, and torsion for which they are designed.

Hooke's law states that *within the limits of perfect elasticity, strain is directly proportional to stress.* This is the principle upon which a spring balance operates: the amount the spring is stretched (or compressed) is directly proportional to the force applied. Thus, if 600 pounds will compress a coil spring 3 inches, 1,200 pounds will compress it twice as far, or 6 inches.

From the standpoint of conservation of energy, the spring is practically 100 percent efficient because it can return practically all of the energy stored in it on distortion if its elastic limit is not exceeded.

Application of Principle

1. Employ springs as a means of absorbing, storing, and imparting mechanical energy. Activities involving the measurement of the energy in springs might include the following:
   a. Test the tension of a screen door spring with a scale and record the pounds pull at various lengths as the spring is stretched.
   b. Test compression springs, such as internal-combustion engine valve springs, on a valve-spring tester, again noting the force required to compress the spring and the change in the length or height of the spring.
   c. Check the torque on a torsion bar with either a scale and lever or a torque wrench.
2. Pursue the method by which the spring is actuated. Some of the methods are as follows:
   a. Use a cam (like that used in the internal-combustion engine) to actuate the valve.
   b. Apply pressure, either hydraulic or pneumatic, to push on a valve (for example, check valves in a fuel pump).
   c. Use a twisting effort, such as the torsion bar or curtain roll, to demonstrate spring action.
3. Gather a variety of springs and identify them as to type (helical, spiral, or leaf); function (to absorb, store, or impart energy); or force which they counteract or react to (compression, tension, or torsion).

Unit 9 — CLUTCHES

The purpose of a clutch is to permit the coupling or uncoupling of a power source (engine or motor) and the drive unit. In an automobile with a standard (not automatic) transmission, the clutch makes it possible to transmit the power from the engine through the power train to the wheels. The clutch utilizes the scientific principle of friction. When the clutch is in a coupled position (engaged), it provides the link which allows power to flow from the engine to the rear wheels. In the uncoupled position (disengaged), it does not permit power to flow. When the clutch is disengaged, the gear may be shifted easily. When the clutch is gradually engaged, with the automobile in gear, the vehicle moves smoothly in the selected direction.

14598

Classifications of clutches and examples of each include (1) the disk clutch, used in automobile transmission couplings; (2) the cone clutch, used in standard transmission synchronizers and engine-lathe controls; (3) the overrunning clutch, used in starter drives and automatic transmissions; (4) the sprag clutch, used in automatic transmissions; (5) the ratchet-dog clutch, used in automobile bumper jacks; and (6) the centrifugal clutch, used in motorcycles, lawnmowers, and go-carts.

All automobile clutches are similar in construction and operation; they are classified as single- or multiple-disk. The single disk is most widely used. Frictional contact in the clutch is made between two smooth, metallic driving surfaces and facings riveted to a driven disk. Pressure springs hold the flywheel, pressure plate, and the friction disk together. The hub of the friction disk is splined to the transmission shaft. Depressing the clutch pedal releases the spring presure, and uncoupling takes place. The flywheel, pressure plates, and the friction disk then turn independently. Releasing the clutch pedal engages the units, and the vehicle moves.

Scientific Principle Involved: Sliding Friction

One scientific principle involved in the operation of a clutch is sliding friction. This friction acts parallel to the surfaces which are sliding over one another and in the direction opposite to that of the motion. The degree of friction depends upon the materials and their surfaces. Sliding friction occurs between the brake lining and the brake drum on a

The illustration presented above gives an exploded view of the clutch unit used in the three-wheel Cushman gasoline truckster (Cushman Motors, Lincoln, Nebraska).

14599

car. It also occurs when two facings on the clutch are pressed between the flywheel and the pressure plate. When the friction becomes great enough between the two surfaces, slippage is almost nil. The two most important factors in this frictional force are the nature of the surfaces involved and the force pressing the surfaces together. Clutch efficiency is, therefore, dependent on the clutch's ability to transmit power from the driver to the driven through friction and, conversely, on its ability to separate the driven from the driver and avoid friction.

Application of Principle

1. Raise an automobile with a bumper jack. Examine the ratchet-dog clutch and observe it as it operates in the jack.
2. Check the operation of a coaster brake on a bicycle; this overrunning clutch stops the bicycle as increasing pressure is applied by the rider's foot on the pedal.
3. Turn the tuning knob on a radio to either the extreme left or extreme right position; continue turning the knob and note the slippage that occurs. (This is an application of the friction-clutch principle.)
4. Check cone-clutch assemblies on engine and woodworking lathes.
5. Examine, disassemble, and reassemble an automobile clutch assembly. Identify the various parts and study their functions.

Unit 10 — DYNAMOMETERS

The dynamometer is a device for determining the actual horsepower (hp) or torque (twisting in foot-pounds) that is available at the crankshaft of an internal-combustion engine or at the driving wheels of a vehicle. Dynamometers may be grouped as follows according to the three methods used to provide load: (1) the use of an electrical generator, using an electrical load; (2) the use of liquids under pressure, using a hydraulic load; and (3) the use of a mechanical shoe or disk brake, using a frictional load.

For the testing of automotive-type equipment, the electrical-load dynamometer has proven most practical. This unit is constructed to measure the power available at the driving wheels of the vehicle. Floor-mounted rollers connected to an electrical generator are driven by the wheels of the vehicle. The voltage and amperage (wattage) output of the generator circuit is instrumented to indicate the horsepower and torque at any given horsepower or engine revolutions per minute (rpm) according to the formula $Hp = volts \times amperes \div 746$, or $watts \div 746$, 1 horsepower equaling 746 watts.

In this testing it is necessary to take into consideration that the power actually measurable at the crankshaft of the engine would be much greater than at the driving wheels because of the power losses in the power-transmission train.

Electrical-load dynamometers and, occasionally, hydraulic-load dynamometers, are available that couple the engine unit directly to the dynamometer for very accurate engine evaluation.

The frictional and hydraulic-load dynamometers couple the crankshaft of the engine to a lever arm that bears on a weighing scale. The engine is placed under load at a given rpm by the frictional-brake unit or hydraulic pump while the lever is pressing on the scale. The torque in foot-pounds is determined by the simple formula which states that torque (in foot-pounds) equals lever arm length in feet, scale reading in pounds. Thus, $Hp = torque \times rpm\ of\ engine \div 33{,}000$. (The figure 33,000 comes from James Watt's determination, based on careful measurement, that a strong horse can do about 33,000 foot-pounds of work per minute.)

Scientific Principle Involved: Horsepower

Work can be accomplished by sliding, rolling, lifting, or rotating anything having mass. Work is done when a force acts on matter and changes its motion. A force (energy) can be supplied by a natural phenomenon (such as wind) or by a mechanical device (such as an engine or an electrical motor). In relation to power output, a force

14606

must have a time factor or rate of doing work. Power represents a mass being displaced over a distance in a certain period of time. Power is a function of the time it takes to accomplish work (force X distance moved). For the use of science and industry, it has been established that a horsepower represents the lifting of 33,000 pounds 1 foot in 1 minute. The formula is expressed as *Hp = weight in pounds X distance moved in feet ÷ 33,000 X time in minutes.*

Application of Principle

1. A simple dynamometer for small gasoline engines of about 1 horsepower can be constructed from a typical 12-volt automotive alternator or direct-current generator with a regulator. A variable resistor or carbon pile of .1 or 1 ohm capable of dissipating at least 1,500 watts should be provided for the generator load circuit. A tachometer suitable to the engine should be provided with an accurate voltmeter and ammeter. At a given rpm the load should be adjusted to give a slight drop in voltage with a maximum ampere indication.
2. A hydraulic dynamometer can be constructed by driving a hydraulic pump or water pump with a small engine and measuring the pressure and flow developed through an orifice at a given rpm.
3. A frictional dynamometer can be constructed from an automobile brake and a scale. Measure the foot-pounds of torque produced at a given rpm.
4. An experimental or demonstration dynamometer for small engines can be constructed similar to the one illustrated.

When this type of dynamometer is used, the engine must be started with no load on the generator. Once the engine is operating at peak performance, the electrical load is thrown into the circuit. The students can (a) record the voltage and amperage; (b) multiply these readings to determine the wattage output of the engine-generator; and (c) divide this product (wattage) by 746 to determine the horsepower.

In one high school the students calculate the actual horsepower of automobiles and test the performance of "tuned" and "untuned" engines by making use of a highway going over a hill of known elevation. By knowing the height of the hill, the total weight of the vehicle, and the time required to accomplish this run, the students figure the total foot-pounds of work accomplished per minute; by dividing the total foot-pounds of work per minute by 33,000, the students figure the average horsepower actually developed.

SECTION III
STEAM POWER

Unit 11 — STEAM ENGINES AND TURBINES

When water is boiled and changed into steam, water expands about 1,700 times. If this steam is collected in a closed container and is not permitted to expand to its full volume, the pressure (and the boiling temperature of the water) will increase. When this pressure is released, it has the potential to do work. In this way heat energy (used to boil the water) can be converted into mechanical energy. The steam can be used to drive the piston of a steam engine or to drive the blades of a steam turbine. Since the generation of steam is usually done by burning the fuel outside the engine, most steam engines and steam turbines are external-combustion engines. Wood, coal, or oil is used as fuel. Nuclear power plants use heat from a nuclear reactor to produce steam.

The steam turbine has become one of man's most important sources of power. Approximately 80 percent of all electricity used in the United States is generated by steam turbines. Many ships use steam turbines to drive their giant propellers.

In a large steam turbine, the two main parts are the rotor and the stator. The rotor is a long shaft on which are mounted wheels containing a large number of sets of blades. The stator, which encases the rotor, contains a large number of fixed nozzles. Steam from the nozzles exerts pressure against the sets of blades, causing the rotor to turn. The diameters of both the rotor and the stator are larger near the outlet end to allow for the expansion of the steam. The pitch and size of the blades vary throughout the length of the turbine so that the expansive force of the steam is used efficiently.

Steam also has other valuable functions. It can be used to heat buildings and clean automotive or

In the steam engine of James Watt, the steam pushes the piston first on one end, then on the other end, so that there is power when the piston slides forward as well as when it slides backward.

14602

14603

industrial equipment. At one time the steam engine was the source of power used in automobiles. At present, in an effort to use fuel more efficiently and reduce smog, experiments are being conducted to develop a compact steam engine or turbine that can serve as a source of power for the automobile.

Scientific Principle Involved: Conversion of Heat

Whenever a gas is trapped in a confined container and the temperature is increased, the pressure increases. This pressure can be used to apply a force which can move pistons, rotate blades, or provide force for other purposes. Steam engines and turbines are heat engines using external combustion. They are able to change heat energy to mechanical energy.

Application of Principle

1. Demonstrate that the energy of steam can move an object. Punch holes diagonally from each other near two corners of a metal (spice) can. (These holes should be about one-half inch above the bottom and just around the corner on the broad surface of the can.) Put about two tablespoonfuls of water in the can and close the opening in the top. Hang the can by a thread. Apply heat to the bottom of the can.
2. Construct a simple steam turbine by using a pressure cooker or a tin can to generate steam. Fasten a small tube to the pressure cooker outlet or outlet of the constructed boiler and direct the steam to the blades of a turbine. (The turbine can consist of a few blades mounted on a small shaft or a squirrel-cage-type blower.)

The energy of steam can be made to move an object.

SECTION IV
THERMAL POWER

Unit 12 — HIGH-ENERGY RATE FORMING

High-energy rate forming has developed from an interesting curiosity to a metalworking reality. There are extensive possibilities for the application of this process in a wide variety of industries. High-energy rate forming of metals now includes the operations of forming, sizing, flanging, engraving, compacting, welding, hardening, and controlled cutting. Some of these operations are used commercially; others are still in the experimental stage. The material used in these operations may be in bulk, plate, sheet, or powder form. There are four methods of high-energy rate forming: explosive, electrohydraulic, electromagnetic, and pneumatic-mechanical.

Low and high explosives are used in *explosive forming.* Low-explosive powders do not actually explode but burn at a rate of several hundred feet per second and are accompanied by the rapid evolution of gas. Expansion of the gas, through either air or some other medium, such as water or a hydraulic plunger, forces the blank to the contour of the die. Low explosives are used in a closed chamber. High explosives detonate in a few millionths of a second and produce shock waves whose magnitude is in millions of pounds per square inch (psi). The charge is suspended in a medium over the material to be formed. The medium used to conduct the shock waves is usually air or water, but oil, plastics, powdered talc, and clay are also used. The charge may be shaped to direct the shock waves to specific areas of the blank. Explosive forming is used in extruding, forging, shearing, and blanking. Metal and ceramic powders have been successfully compacted by the technique of explosive forming.

Electrohydraulic forming is sometimes referred to as hydrospark forming or electric-discharge forming. The discharge of an electric spark under water produces a shock wave with sufficient energy to form metal parts. Forces equal to 6,000 horsepower (hp) within 40 millionths of a second are possible at present. The equipment used in electrohydraulic forming consists basically of a high-voltage power supply, capacitors for storing the charge, a discharge switch, and a coaxial electrode. The force can be varied by changing the voltage. The advantages of electrohydraulic forming over many other forming processes are greater safety, more precise control, and lower cost.

Another concept in high-energy forming is *magnetic forming.* Electrical energy produces magnetism which acts as the forming force. The magnetic pulses, lasting only six millionths of a second, exert pressure up to 560,000 pounds per

square inch. Magnetic forming has three classifications of forming: compression, expansion, and hammer. This forming method has the distinct advantage of forming material without marring or scratching the surface, thus eliminating further finishing operations. It can perform as many as 600 forming operations per hour. Magnetic forming is used to (1) form tubing into precise and difficult shapes; (2) expand tubing into bushings, hubs, and split dies; (3) swage inserts, fittings, and terminals into many different parts, including rope, cables, and other parts; and (4) coin, shear, and blank.

The Hyge machine, built by Convair and used for *pneumatic-mechanical forming,* is actuated by 2,000 pounds per square inch of nitrogen. When the compressed gas is suddenly released from its storage chamber, it drives a piston-column assembly at high velocity into a liquid medium which acts against the blank in the die. The machine also has been used to extrude tungsten, forge ferrous and nonferrous alloys, and compact ceramic and metal powders. Advantages of pneumatic-mechanical forming over many other forming processes are the elimination of explosives as the power source and the high repeatability of the operation.

Scientific Principles Involved: Work, Power, Energy, Force

The four methods of high-energy rate forming covered in this unit deal primarily with the scientific principles relating to energy, force, power, and work. Energy is defined as the ability to do work (or the capacity for doing work). In mechanics there are two forms of energy, kinetic and potential. Kinetic energy is energy due to the motion of a mass. A moving automobile, exploding gunpowder leaving a shell, compressed gas released from a storage chamber, and an electrical charge leaving a capacitor all have kinetic energy. Potential energy is stored energy. A coiled mainspring of a watch and a charged capacitor have potential energy. Force produces or prevents motion. It is also defined as a push or pull. Work is done when force acts on matter and changes its motion or when force moves an object against an opposing force. Power is the rate of doing work. In high-energy rate forming, the work accomplished depends upon the energy which produces the force.

Application of Principles

High-energy rate forming can be demonstrated through the use of an explosive-forming device which employs a .22 caliber cartridge (blank) as the power source. The explosive-forming device has four parts: frame, bolt, explosion chamber, and die. (See the assembly drawing.) Power loads (cartridge-type powder charges) are available in various ratings: extra light, light, medium, heavy, extra heavy, and magnum. Medium loads are satisfactory for use with sheet metals such as .015-inch tinplate, .030-inch annealed copper, and .035-inch soft aluminum. Efficiency can be increased by pulling a vacuum in the die cavity; however, the unit works well enough with only air relief holes in the die cavity.

The frame is made from two pieces of SAE 1020 cold-finished steel measuring $\frac{5}{8}'' \times 2'' \times 6''$. The two pieces should be clamped together during drilling to maintain alignment. Four pieces of $\frac{3}{8}$-inch steel pipe are used for the frame spacers. The four spacers must be precisely the same length to prevent distortion of the frame. The top plate, base plate, and four spacers are assembled and secured with four $\frac{3}{8}''$ (16 NC) $\times$ 5″ machine screws.

The bolt assembly is made from a $\frac{5}{8}''$ (11 NC) $\times$ 3″ alloy steel hexagon-head cap screw. The firing pin and firing pin retainer are made from an oil-hardened drill rod and both are heat-treated to 52Rc (Rockwell). If heat-treating facilities are not available, parts 1 and 2 may be made from heat-treated SAE 4140 steel. This material is machinable and tough enough to serve the purpose well. The firing pin retainer also serves as the bolt handle. The die-centering pin at the bottom of the frame is a modified $\frac{3}{8}''$ (16 NC) $\times \frac{1}{2}''$ round-head machine screw and keeps the die centered in the frame.

The explosion chamber is made from 1020 steel. It is important to maintain reasonable concentricity in all machined parts and to leave the cartridge chamber undersize for later reaming by a gunsmith. The die cavity is also made from 1020 steel. The size of the air relief holes is determined by experimentation.

When all parts have been completed and before heat treatment of the firing pin and firing pin retainer (if a drill rod is used), the unit should be assembled, and the assembly should be checked by a qualified gunsmith. In particular he should check the firing pin length, check the head space, and ream the chamber for .22 caliber. The charge for this service varies, but generally is less than the cost of a chambering reamer.

14605 14604

The material to be formed should be cut to 2¼-inch diameter and placed between the explosion chamber and the die. A power load should then be inserted into the chamber, this assembly should be placed in the frame, and the bolt should be turned down securely.

For safety the unit is so designed that the explosion chamber is recessed into a counterbore in the die cavity, and the bolt enters a counterbore in the explosion chamber. It is practically impossible to discharge a power load unless all parts have been securely and properly assembled.

The power load is discharged by striking the firing pin sharply but *lightly* with a small hammer. The expended power load may be extracted with a 6-inch piece of ⅛-inch brazing rod.

Unit 13 — POWDER-ACTUATED TOOLS

Among the most interesting of the recently developed tools are powder-actuated tools. These tools use energy from the firing of a powder charge to drive a fastener into concrete or steel. Many attempts were made to use explosive energy for this purpose as early as the turn of the century, but not until 1945 was a method developed that was commercially practical. Today, labor on hundreds of fastening jobs is greatly reduced by powder-actuated tools. This method makes use of a stud-driving tool, a powder charge, and a fastener (stud). Powder-actuated tools have two primary functions. First, they set threaded studs into concrete and steel for fastening removable installations. Second, they drive nail-like studs through materials into concrete and steel for making permanent installations.

Since powder-actuated tools make use of the high-pressure gases developed by the confined burning of powder (nitrocellulose propellant), they are potentially as dangerous as any other form of explosive. However, improvements in these tools since they were first introduced have made them relatively safe to operate as long as the prescribed precautions are observed. Because safety is such an important factor in operating powder-actuated tools, all operators must be certified before they may fire an explosive tool. To obtain a certificate, an operator must pass a written test on the safe operation and care of the tool.

The first safety practice to be observed is to read and understand the instruction manual provided for the particular powder-actuated tool before attempting to operate the tool. These manuals describe the components of the stud-driver, the loading and firing cycle of the tool, the parts list and parts numbers, the use of the extension, the use of the shield, the proper maintenance of the tool, and the particular precautions to be observed. All of the safety precautions presented in a manual are important and must be observed in order to prevent injury to the operator or to a bystander. Certain of these precautions take precedence over others. The general sequence of importance of these precautions is indicated in the safety instructions that follow:

1. Use a positive guide to insure alignment when setting a fastener through a previously prepared hole in steel.
2. Always fire from a fully shielded position as protection against ricochet.
3. Use an extension only when the safety control rod is accurately set to prevent firing at an angle.
4. Make sure before firing that the fastener does not have sufficient power to drive completely through the material.
5. Always set the fastener 3 inches or more from the edge of concrete.
6. Always set the fastener ½ inch or more from the edge of steel.
7. Use only a factory-recommended fixture for any special fastening as described in the manufacturer's instruction manual.
8. Allow at least 30 seconds before removing a tool from the work surface in the event it does not fire; then remove the powder charge and dispose of it safely.
9. Be sure the tool is unloaded when not in use. If an operator decides not to fire the tool, he must unload it.
10. Never fire into cast iron, tile, high carbon steel, or other hard or brittle materials.

Despite the many hundreds of applications performed daily by a powder-actuated tool, there are only a few simple basic rules that govern the system and make it possible for the operator to do good work. These rules are as follows:

1. Know the material to be penetrated. If a common nail can be hammered into the base material, don't use a powder-actuated tool.
2. Select the proper fastener for the job. Consider only the section of the fastener that is to be imbedded under the work surface of the material since the section above the work surface of the material will be determined by application requirements. When selecting a fastener for concrete, choose one that will penetrate into the concrete a minimum distance of eight times the diameter of the shank of the fastener. A light-duty fastener with a shank diameter of 5/32 inch must penetrate 1 ¼ inches; a heavy-duty fastener with a shank diameter of ¼ inch must penetrate 2 inches. When selecting a fastener for steel, remember that the whole point of the fastener must appear through the reverse side of the steel plate.

14608

3. When selecting a powder charge to set a fastener into either steel or concrete, or when determining how far to insert the stud into the barrel, always use the weakest powder charge or insert the stud a fair distance into the barrel for the first fastening. Learn the color codes some manufacturers have placed on the powder charges, for the different colors designate powder charges of varying intensity. The colors should be memorized for immediate recognition. The power of the charge is indicated by the color of the wads in the mouth of the cartridge case as well as on the box or container in which they are packed.
4. Know the holding power of the fastener. A powder-actuated tool is designed to maintain a balance in the relationship of the power of the cartridge to the length and diameter of the fastener shank. If a fastener is selected within the proper limits – that is, eight diameters into concrete or the whole point through the reverse side of steel – the correct holding powers will generally result.

Scientific Principle Involved: Expansion of Gases

The propelling force of the powder charge (nitrocellulose, the successor to gunpowder/black powder) results from the rapid burning and evolvement of hot gases that exert a sustained forward force or pressure on the missile or projectile. The rapid conversion of the powder charge into hot gases that have a larger volume than the volume of

the original charge overbalances the restraining pressure of the surrounding matter.

Application of Principle

Since the powder charge and fastener are potentially as dangerous as ammunition, the powder-actuated tool must be operated by a person with an operator's certificate. A qualified teacher, construction worker, or manufacturer's representative should demonstrate the use of this tool. The explosive-forming device (referred to in Unit 12, "High-Energy Rate Forming") can be used to demonstrate the propelling force of a powder charge.

Unit 14 — JET AND ROCKET ENGINES

Jet and rocket engines are internal-combustion engines. They operate through the application of Newton's third law of motion: *For every action there is an equal and opposite reaction.* Burned gases leave the engines with great force. The opposite reaction is an equal thrust in a forward direction. As a result the jet or rocket engine is pushed (thrust) forward, carrying the plane or rocket with it.

Jet and rocket engines operate identically in relation to Newton's law. However, they differ in the way their fuel is prepared for combustion. A jet engine sucks in air from the atmosphere and mixes it with the fuel for burning. A rocket carries its own air in the form of an oxidizer and operates in space, where there is no atmosphere.

The jet engine is defined further as one which propels itself by the same gases that convert the fuel's thermal energy into mechanical work — turning the air compressor turbine.

There are three types of jet engines using the same basic principles of operation: the turbojet, the turbofan, and the ramjet engines. They are described as follows:

1. The *turbojet or gas turbine engine* is thought of as a "pure" jet engine because it most closely follows the above description. In the turbojet engine, air is brought into the front of the engine by a compressor. The compressor forces the air into the center section of the engine, where fuel is added and ignited. The burning fuel increases the temperature and the pressure in the chamber. The gases, therefore, exert a heavy force in all directions. The compressor prevents the gas from escaping out the front. As the gas escapes out the rear, it drives a turbine. The only function of the turbine is to drive the compressor. As the gases escape out the exhaust, a forward push is given to the engine. This push is called thrust, which is measured in pounds. Thrust is, therefore, the forward push (force) resulting from the pressure in the combustion chamber. In the turboprop engine the combustion gas turns a propeller as well as a compressor. Propulsion power in this case comes from the propeller. The exhausting gas, depleted of most of its energy in operating the prop and the turbine, adds little thrust to the turboprop engine.
2. The *turbofan engine,* one of the most widely used engines, modifies the operation of the

A steam catapult is used to launch a jet aircraft from the USS Coral Sea (U.S. Navy photograph).

14611 0001

turbojet engine. The turbofan engine is able to process greater quantities of air, provide increased thrust, and operate at lower temperatures. This improvement is accomplished by providing a bypass around the combustion chamber for a portion of the incoming air. This air is shunted to the rear of the engine, where it combines with the heated gases. The mixing of the gases makes more efficient use of the available heat, producing greater thrust.

3. The *ramjet engine* does not even use a compressor, has no moving parts, and requires high speed before it can operate; it cannot be started from rest. The forward motion of the engine brings in the air. The shape of the combustion chamber prevents the air already in the chamber from being compressed by the incoming air. Fuel is added and ignited, and thrust is produced in the same manner as in the turbojet engine. The incoming rush of air prevents the forward exhaust of the burned gas. At high speeds the ramjet engine is more efficient and trouble free than the turbojet engine; however, the ramjet engine cannot be used when the plane is standing still or is traveling at slow speeds. Future jet engines may take advantage of both turbojet and ramjet features. A combination engine called a turboramjet engine has been proposed. It would take off and operate as a turbojet engine. When sufficient speed is reached, it would operate as a ramjet.

The rocket engine uses the same principles of operation which control the jet engine. However, it operates independent of air, carrying a supply of both fuel and oxidizer. Since the "reaction principle" of motion does not require atmosphere, the rocket engine operates effectively in space. In operation, oxidizer and fuel are ignited in a combustion chamber. The resulting gases are heated to a very high temperature, producing a high pressure. As the gases escape from the rear of the engine, a strong forward thrust propels the rocket.

The same principle of operation that is applied to the turboprop engines of planes can be applied to gas turbine engines in automobiles. In these engines nearly all of the force of the escaping gas is absorbed by the turbine. The turbine serves a dual function. Part of the energy is used to drive the compressor bringing in the air needed for combustion. However, the larger portion of the energy is used to rotate the airplane propeller when the turboprop engine is used or to rotate the wheels of the automobile when the gas turbine is used.

Scientific Principle Involved: Newton's Laws

Gas confined within a container exerts pressure equally in every direction. As long as the container is sealed, the forces resulting from the pressure are in balance. If the pressure is relieved at any point, however, the force at that point will drop. As a result the force opposite the reduced force will cause movement or apply an unbalanced force in a direction opposite that of the relieved pressure. This same principle can be identified in a different manner: for every action there is an equal and opposite reaction. In the case of gas pressure, relief of the pressure (by opening the chamber at that point, exhausting the gas) produces an opposite and equal reaction. The reaction is a push away from the point at which the pressure is released.

Application of Principle

1. Newton's third law of motion (for every action there is an equal and opposite reaction) can be demonstrated by filling a toy balloon with air and releasing the balloon. The balloon goes forward (reaction) with a force equal and opposite to the force of the escaping air.
2. The principle of jet and rocket propulsion can be taught by constructing a small rocket, using a CO_2 cartridge as the engine. The rocket can be operated on a string on the school grounds. The most important consideration for a good flight is to get a hole punched in the cartridge and the rocket released before much of the CO_2 escapes.
3. The thrust of a CO_2 cartridge can be measured by attaching the cartridge to a bicycle wheel and checking the movement of the wheel with a dynamometer.

Unit 15 — GASOLINE TESTING

Two tests used in comparing the power of gasolines are the Full Load Power Test and the Fixed RPM Power Test. The units used in the measurement are foot-pounds of torque (fpt).

A single-cyclinder engine is generally used in testing the power of gasolines. The engine fuel-supply system must be equipped with a quick-change system, which can be made by fitting the fuel line with a glass jar lid in a way that will permit the person performing the test to rapidly interchange jars containing samples of different gasolines.

The engine is equipped with a tachometer, and the load is applied by a dynamometer. Readings of the revolutions per minute (from the tachometer) and foot-pounds of torque (from the dynamometer) are made and recorded for each sample of gasoline for full load power and fixed rpm power.

Directions for performing the tests are as follows:

1. *Full Load Power Test.* Adjust the throttle and dynamometer until maximum readings for both rpm and fpt are observed. Record these readings.
2. *Fixed RPM Power Test.* Adjust the throttle to maintain 2,000 rpm while increasing the load on the engine with the dynamometer. Record the highest fpt reading which can be obtained without dropping below 2,000 rpm.

Today's best gasoline engines reach an efficiency of 25 to 30 percent. Higher efficiency of the engine is obtained by increasing the pressure (compression) of the fuel-air mixture in the cylinder just before it is ignited. However, high compression raises some difficult practical problems, such as making pistons and valves fit perfectly. Also, when the pressure on the gasoline vapor is suddenly increased by the compression of a piston, the gas gets hot. In fact, under high compression the fuel mixture gets hot enough to explode before the spark ignites, causing engines to knock. Chemists have developed a gasoline that can be highly compressed without exploding too soon. High-octane gasoline is highly resistant to knock; low-octane fuel knocks easily. A gasoline is rated by the use of an octane-rating number (ONR). Iso-octane is given a rating of 100 because it is very resistant to knocking. Another fuel, heptane, is given a rating of zero because it knocks easily. A mixture of half iso-octane and half heptane (by volume) has a rating of 50. Iso-octane and heptane are reference fuels used to test and rate unknown fuels.

Scientific Principle Involved: Conversion of Energy

Gasoline (chemical energy) is useful as a fuel for internal-combustion engines because it is easily evaporated and very flammable. A mixture of gasoline vapor and air provided by the carburetor enters the cylinder, the piston moves up to compress it, and an electric spark ignites the compressed mixture. The burning is a fast chemical reaction that produces carbon dioxide (CO_2), water vapor, and a large amount of heat (heat energy). The heat produced expands the CO_2 and water vapor, forcing the piston down. The downward movement of the piston (mechanical energy) turns the crankshaft.

The dynamometer makes use of friction to measure the torque (twisting rotational force) produced by an engine. Force is a push or a pull which tends to produce movement. Friction is the resistance to movement which is observed when two surfaces make contact.

Application of Principle

1. Samples of various grades and brands of gasoline should be given the Full Load Power Test and the Fixed RPM Power Test. The recorded readings should be compared to determine what significant differences of power have been demonstrated, and the various differences in automobile engine design and conditions which affect its fuel requirements should be discussed. Some of the factors which should be in the discussion are compression ratios, carburetors, gasoline octane ratings, spark coils, capacitors, distributor points, spark plugs, and ignition wires. *Note:* Poisonous carbon monoxide is present in the exhaust gases of a running engine. Good ventilation is a "must" to prevent carbon monoxide poisoning whenever an engine is being operated indoors.
2. A fractionating tower can be assembled to distill petroleum. *Note:* It is unsafe to heat petroleum with an open flame above 75 degrees C. Rubber tubes must be connected from the fractionating tower to the collecting bottles. Petroleum warmed to 40 degrees C.

14613

will produce a vapor that when condensed will be pentane gasoline; to 75 degrees C., hexane gasoline.

Unit 16 — CARBURETION

Most American internal-combustion engines use gasoline as fuel. Gasoline is obtained from petroleum and is composed primarily of hydrogen and carbon compounds. By the mixture of correct amounts of gasoline and air and the ignition of this mixture in an engine, power is produced to drive a vehicle. The mixing of gasoline and air in controlled amounts is known as carburetion. The device on automobiles and other units driven by internal-combustion engines that performs this function is called a carburetor. The carburetor performs several specialized functions. The names and brief descriptions of these functions are as follows:

1. *Float circuit.* The major function of the float circuit is to keep the bowl filled with gasoline. As the level of gasoline approaches full, the float rises and cuts off the ingress feed; when the float drops, the valve is opened, allowing the ingress feed to open.
2. *Idle and low-speed circuit.* This circuit operates when the throttle is closed or nearly closed. At this time only a small amount of air can flow through the carburetor air horn (air intake), causing a limited mixture to be supplied to the engine.
3. *High-speed, part-load circuit.* As the throttle is opened for high speed, it moves past the low-speed port in the carburetor and allows air to pass the air horn in a sufficient quantity to furnish a mixture adequate for the demanding conditions.
4. *High-speed, full-power circuit.* This circuit is designed to do what its title suggests. The mixture supplied is satisfactory for engine operation from partly open to nearly wide-open throttle. When the throttle is opened wide, a metering rod and jet assembly allow more gasoline to pass a point and provide an enriched mixture.
5. *Accelerating pump circuit.* This circuit carries the engine through the closed throttle to open-throttle transition period. The transition period is ofter referred to as a "flat spot" in engine performance.
6. *Choke circuit.* This circuit is designed to cause the carburetor to deliver great amounts of fuel for starting when the engine is cold. The circuit can be controlled electrically, thermostatically, or manually.

A great deal of air passes through the carburetor and engine. Air is likely to contain a great amount of dust and grit. These impurities, if they entered the engine, could cause serious engine damage. All air entering the engine through the carburetor must first pass through an air cleaner. Air cleaners contain filter material (fine-mesh metal threads or ribbons, special paper, cellulose fiber, or polyurethane) or oil reservoirs to remove dust and grit from the incoming air.

Scientific Principle Involved: Bernoulli's Principle

When a fluid is undergoing a change in velocity, the pressure, measured at right angles to the direction of flow, is lowest at the point of highest velocity. A venturi is built in the air tube leading to the jets in a carburetor. The air moves through the venturi, causing a low pressure as it reaches the area of the tube, where the diameter is less

The illustration presented above gives an exploded view of the carburetor used in the three-wheel Cushman truckster and haulster (Cushman Motors, Lincoln, Nebraska).

14615

The venturi (left) is a constricted tube which causes the velocity of the air to increase and the pressure to decrease. A carburetor (right) illustrates the use of the venturi (Briggs & Stratton Corp., Milwaukee, Wisconsin).

(constricted). The air pressure in the liquid container (bowl) forces the gas to flow into the tube and mix with the air, where it becomes atomized.

Application of Principle

1. Small, single-cylinder engines lend themselves well to experimentation involving the degree of combustion efficiency and its effect on the engine's operating conditions. Students can vary (a) the throttle-valve setting; (b) the choke-valve setting; and (c) the mixture setting. They can then observe the results in smoothness of operation speed and the quantity and color of exhaust smoke.
2. Students can construct a miniature wind tunnel to measure static and dynamic pressures in the venturi.

Unit 17 — TWO- AND FOUR-CYCLE ENGINES

The source of power for internal-combustion, reciprocating engines is heat-formed by the burning of a combustible mixture of petroleum products and air. In a reciprocating engine this burning takes place in one or more closed cylinders, each containing a piston. Expansion resulting from the heat of combustion applies pressure on the piston. This pressure forces the piston down, turning a shaft by means of a crank and a connecting rod.

In the gasoline engine the fuel is ignited by a spark; in the diesel engine, by the heat of compression. The series of events that takes place to run the engine may occur in one revolution of the crankshaft (two-stroke cycle) or in two revolutions of the crankshaft (four-stroke cycle). The operating cycle consists of the following parts:

1. *Intake.* The mixture of fuel and air is drawn or forced into the cylinder by reducing the cylinder pressure to less than atmospheric pressure or by applying an initial, higher pressure to the fuel charge.
2. *Compression.* The mixture is reduced in volume, or compressed.
3. *Power.* The mixture is ignited by a timed electric spark (gasoline engine) or by the heat of compression (diesel engine). The burning fuel-air mixture expands, forcing the piston down and thus converting the generated chemical energy into mechanical energy.
4. *Exhaust.* The burned gases are exhausted from the cylinder so that a new cycle can begin.

The diesel engine differs from the gasoline engine in that in the diesel engine air alone is drawn into the cylinder during the intake stroke and is then compressed to a much higher degree.

14616

The air is heated by compression. Instead of an electric spark, a finely atomized charge of fuel is injected into the combustion chamber, where it combines with the heated air, causing ignition. The power and exhaust strokes are almost identical to those of the gasoline engine.

Each movement of the piston from top dead center (TDC) to bottom dead center (BDC) is referred to as a stroke. Thus, for every two strokes of the piston, the crankshaft makes one complete revolution, meaning that there will be two revolutions of the crankshaft for each complete four-stroke cycle (intake, compression, power, and exhaust). For the purpose of intake and exhaust, valves are installed in the combustion chamber. The opening and closing of the valves must be synchronized with the movement of the piston on appropriate strokes.

The four-stroke cycle of an internal-combustion engine takes two revolutions of the crankshaft.

The two-stroke cycle of an internal-combustion engine takes one revolution of the crankshaft.

In a two-stroke-cycle engine, the four events take place in two strokes of the piston or one revolution of the crankshaft. Thus, a compressed fuel charge is fired each time a piston reaches TDC; each downward stroke is a power stroke. The incoming fuel-air mixture must be somewhat higher in pressure than the lowest pressure existing in the cylinder. The piston is used as an air pump

14617

for this purpose; the engines are called "crankcase-scavenged."

Scientific Principle Involved: Expansion of Gases

A very important principle in the operation of the two- or four- cycle engine is the expansion of gases or the conversion of chemical energy to heat energy to mechanical energy. Energy is defined as the capacity to do work. The energy is stored in the molecules of gasoline. When the fuel is ignited, energy is released and produces heat, which increases the pressure of the gases above the piston. The piston is pushed down in the cylinder. The downward movement of the piston turns the crankshaft.

Application of Principle

1. Have students do as follows:
   a. Disassemble and assemble two- and four-cycle engines.
   b. Draw on engine schematics (provided by teacher) the flow of air-fuel and exhaust on each of the engine types.
   c. Identify valves, ports, pistons, rods, and other internal parts.
   d. Determine the firing order of an engine.
   e. Find the compression ratio of an engine by using actual measurements.
   f. Determine engine displacement by measuring the bore and stroke.
2. Calculate actual pressure on the top of a piston as a result of the expanding gases.

Single-cylinder, air-cooled, two-cycle engines are used to power a saw, pump, bicycle, and spray-gun compressor (Orline Products, Los Angeles, California).

14618

Unit 18 — WANKEL ENGINES

The recently developed Wankel internal-combustion engine is relatively small, lightweight, and inexpensive to manufacture. It is extremely versatile: there is almost no limit on compression ratio, maximum revolutions per minute, type of fuel feed, and method of cooling. The Wankel engine is capable of running at high speeds for long periods of time. It is very successful in cutting down friction by a reduction in the number of moving parts.

As the rotor "piston" of the Wankel engine turns, it forms chambers between the three sides of the rotor and the wall of the housing. The shape, size, and position of the chambers are constantly being altered by the rotor's rotation. Cycles of intake, compression, power, and exhaust are going on simultaneously around the rotor when the engine is running. There are three power impulses for each rotor revolution.

As the rotor opens the intake port, which has no speed-restricting valve mechanism, the fuel-air mixture is drawn in. The rotor continues turning, closing the intake port by passing beyond it. Then the compression begins, followed by ignition, combustion, and expansion for the power stroke until the exhaust port is uncovered. The exhaust cycle then takes place, again with no speed-restricting valve mechanism. The entire operation cycle is thus completed.

During the combustion cycle the rotor of the Wankel engine turns and forms chambers between the three sides of the rotor and the wall of the housing (Curtiss-Wright Corp.).

The new Wankel marine engine uses twin rotors.

14619

Scientific Principle Involved: Movement of Inertia

A body continues in its state of rest or uniform motion unless an unbalanced force acts on it (Newton's first law of motion). A wheel mounted on an axle will not start to rotate unless a torque is applied to the wheel. A wheel which is spinning will continue to spin at constant angular velocity unless a torque acts on it. In both cases the wheel is in equilibrium. Thus, Newton's first law of motion also applies to rotary motion.

A rotating flywheel helps maintain a constant angular velocity of the crankshaft of a Wankel or conventional internal-combustion engine. The moment of inertia of a flywheel is large. Torques acting on it do not produce rapid changes in its angular momentum. As the torque from the combustion in each chamber or cylinder tends to accelerate the crankshaft, the flywheel provides a torque which resists this action. But as the torques from each chamber or cylinder where compression is occurring tend to decelerate the crankshaft, the flywheel provides a torque which resists this action also. The flywheel tends to maintain a uniform rate of crankshaft rotation.

Application of Principle

The Wankel engine, which has not been adopted for use in any American vehicle, is being used in NSU sports cars and marine engines manufactured in Germany. Several companies have been licensed to manufacture the engine, including Curtiss-Wright in the United States, Daimler-Benz and others in Germany, Perkins in England, and Kogyo in Japan. Most of these companies will provide drawings and photographs on request.

Unit 19 — THERMOSTATS

A thermostat is a device that is used to control temperature. It responds directly to a change in temperature and is usually set so that it maintains a desired temperature level. Most thermostats are used to open or close electrical circuits or to control the flow of liquids or gases.

Thermostats are used in the home to control the temperatures of heating systems, air conditioners, refrigerators, electric irons, stove ovens, and electric blankets. In the automobile a thermostat restricts the flow of the coolant in the radiator until the correct temperature of the engine is reached. The automobile heater, as well as the refrigeration system, uses the thermostat as a temperature-control device.

One of the most common thermostats uses a bimetallic strip that operates on the expansion and contraction of two different metals. When the temperature changes, the two metals expand or contract unequally. This causes the bimetallic strip to bend in the form of an arc. The bending of the strip can be used to open or close a circuit.

In a home-heating system the thermostat is set to open or close the circuit controlling the valve that turns the heater on or off at the desired temperature. A similar unit is used in the electric iron so that the circuit is broken and the iron is shut off when the proper temperature is reached. If the iron becomes too cool, the thermostat closes the electrical circuit and the iron heats up again.

In the automobile engine the thermostat is placed in the top of the block to close off the flow of coolant when the engine is cold. This closure causes the engine to reach operating temperature more quickly. The thermostat operates a valve so that, when the engine warms the coolant to the set temperature of the thermostat, the valve opens to permit normal circulation. Coolant thermostats are of various types which normally use the expansion of a liquid or wax to control the engine temperature. One type, called a bellows thermostat, contains a liquid that evaporates with increasing temperature and causes the pressure inside the bellows to expand and push the valve open. Another type, called a butterfly thermostat, uses a wax pellet, which also expands with increasing temperature to open the valve to permit the coolant to flow through the radiator.

1208114620

Scientific Principle Involved: Thermal Expansion

Heat is the kinetic energy of randomly moving molecules. Adding heat to a substance causes the molecules to move more rapidly and produce a greater tendency for the molecules to overcome their mutual attracting forces and to move farther apart. Different solids have individual rates of expansion and different melting points because they are composed of unrelated molecules which are bonded together in different ways. Liquids also have various expansion rates and boiling points; but liquids in general expand more than solids under the same changes in temperature since liquid molecules move more freely. The molecules of gases are so far apart and free to move that the thermal expansion rates for gases are many times greater than those for liquids or solids.

Thermostatic controls in the form of spiral springs, such as those used to actuate the heat-riser valve in the automobile exhaust system, depend on the expansion of the metal in the coil to relax the tension of the spring.

Since brass expands about twice as much as steel, bimetallic bars made of these inexpensive metals, bonded together, make sensitive thermostatic controls which can also conduct electricity and withstand high temperatures.

The two different metals in the thermostat expand unequally when the temperature rises, causing the closed contact points (1) to open (2).

Thermostatic controls which operate on the principle of thermal expansion of liquids and gases are generally more sensitive than those dependent on solids because of their high expansion rates. Gases and vapors are particularly useful in thermostats because their molecules, which are uniformly distributed, exert their pressure equally in all directions to all parts of the sealed container.

Application of Principle

1. Secure one or more thermostats from automobiles, a container for boiling water, a thermometer, and a heat source. Suspend the thermostat and thermometer in the container of water and increase the temperature of the water. Note the action of the thermostat as the temperature of the water approaches the temperature stamped on the thermostat. Record the temperature at which the thermostat begins to open, continue to observe the action of the thermostat, and record the temperature at which it is fully open. Discuss the thermostat as a means of control in the cooling system of the internal-combustion engine.

2. Conduct the same type of experiment by using the spiral spring found on the heat riser in the exhaust system of the automotive-type internal-combustion engine. Note that the application of heat to this spring will cause it to actuate the control valve, an action that can be readily observed when heating the spiral spring in the automatic choke on a carburetor. Observe that when heat is applied to this spring, the choke valve moves from the closed to the open position.

3. Note other applications of thermostats in electric irons, circuit breakers, and many other heat-controlled appliances. Obtain the thermostat from an electric iron or a circuit breaker from an automobile electrical system and either connect these units into an electrical circuit with a sufficient load to actuate them or apply heat directly and observe their action.

Unit 20 — WELDING PROCESSES

Welding is the process of joining metal parts by directing heat to melt and fuse parts together. When heat alone is used, the operation is called fusion welding. In some welding processes pressure is used to help join the metals. Many welds require that extra metal be added to the weld by melting a metal rod into the molten puddle.

Industry uses welding to fasten parts together permanently and to make repairs on broken equipment. Many buildings, bridges, and ships are fabricated by welding. The automobile has parts that are welded together; in "tooling up" for an automobile, the manufacturer spends considerable time in arranging for special welding equipment to fabricate many of its parts. As a means of fabrication, welding has proven fast, dependable, and flexible. It has made possible the simplification of design and the elimination of costly machining processes. The three most common methods of welding are gas, arc, and resistance welding.

Gas welding is accomplished by mixing oxygen and acetylene in the body of a welding torch and then lighting the gaseous mixture at the tip. The oxygen-acetylene flame produces a temperature of 6,300 degrees F. After properly adjusting the flame, the welder heats the metal part by holding the flame near the metal until a molten puddle forms. Then he applies the welding rod to build up the weld. One of the advantages of gas-welding equipment is that through the use of a special torch the flame can be used to cut metals.

In arc welding the electric power comes from either an electric generator or a transformer. One cable from the source of power is connected to the metal objects to be welded, and the other is connected to the holder that clamps the electrode. The welder strikes an arc by touching the metal part to be welded with the electrode. The arc produces a temperature of about 9,000 degrees F. The operator feeds the electrode into the joint, forming a bead as it is moved along the surface.

Spot welding, which is usually a method of resistance welding, is employed a great deal in industry to join sheet-metal parts. The pieces of metal are placed together and clamped under pressure between the tips of two electrodes. A large amount of current passes between the electrodes and fuses the metal pieces together at the point where the current passes through the metal.

Brazing, involving the use of gas-welding equipment, is not considered a method of welding. It is called hard soldering since the piece to be brazed is not melted. Instead, the brazing rod is melted into the edges of the pieces to be joined. This process is used in repairing broken parts because there is very little danger that any of the original parts will be damaged.

Safety Instructions

1. Obtain permission from your teacher before using welding equipment.
2. Make sure you have ample ventilation.
3. Be sure that you wear welding goggles while using oxygen-acetylene welding equipment. All assistants and observers must also wear welding goggles.
4. Wear a helmet with a proper observation window, a pair of treated gauntlet gloves, and a treated leather apron while using electric welding equipment. All assistants and observers must also wear this equipment.
5. Keep your sleeves and pants cuffs rolled down and wear a leather jacket while using electric welding equipment.
6. Make sure that welding equipment is working properly and that it is used correctly.

Scientific Principle Involved: Kinetic Molecular Theory

Heat is the kinetic energy of moving molecules. Chemical energy released on the burning of acetylene in the oxyacetylene torch is the source of energy used in gas welding. In the electrical-arc weld, the heat energy is produced by the acceleration of electrons and ions in the electrical field; in the resistance weld the heat is due to the resistance to the movement of electrons in the metal. The purpose of using heat in welding is to increase the temperature of the metals to the point where the kinetic energies of the molecules and atoms of the metals are sufficient to break the bonds which hold these particles together in the crystalline structure of the solid. When these bonds are broken, the metal fuses and the particles move more freely in the liquid state. On cooling, the particles lose kinetic energy and resume relatively fixed positions in the solid state. When these effects occur on the local heating of pieces of metal held closely together, as in spot or seam welding, the result is a strong, solid bond without the addition of more metal. Addition of molten metal, such as in gas and arc welding, allows bonds to form between the

14622

added metal and the fused metal from the surface being welded. The molten metal flows into small spaces between the metal surfaces by capillary action caused by intermolecular forces of cohesion.

In brazing, a different metal with a lower melting point is used as the bonding material. The metals to be brazed are preheated (but not to the melting point) in order to increase the molecular motion, which promotes better penetration of the molecules of the solid metal surfaces by the molecules of the molten metal. The bonds in solids between unlike molecules (adhesion) can be as strong as or stronger than the bonds between like molecules (cohesion). The molten metal used in brazing flows into the small spacing between the metal pieces by capillary action, which is due both to the strong attraction (adhesion) between the molten metal and the solid metal surface and to the high surface tension (cohesion) of the molten metal.

Application of Principle

1. The most effective approach to the application of welding and brazing is to learn the basic technical information and acquire the skills involved in the welding and brazing process.
2. A demonstration of both the gas- and arc-welding processes should include the setup and adjustments necessary for each particular welding operation.
3. An aid which will allow the development of the necessary manipulative skills without the actual use of electrodes, welding or brazing rods, or oxygen and acetylene is a 1-inch dowel or stick approximately 14 to 16 inches in length. A hole is drilled in which an ordinary graphite pencil will fit snugly. The hole should be at an angle which approximates the position of the welding torch or electrode. By an adjustment of the length of the pencil to correspond to either a torch or an electrode, the basic patterns and strokes may be practiced on a piece of paper.

14623

SECTION V
ELECTRICAL POWER

Unit 21 — DRY CELLS: PRIMARY CELLS

One of the most common sources of electrochemical energy is the dry cell (primary cell). Electrical devices such as flashlights, portable radios, and warning flashers on the highways are usually powered by dry cells, which are convenient and flexible power suppliers. Regardless of size a zinc-carbon single dry cell produces 1.5 volts of direct current (DC). The cell is most often made from (1) zinc, which is one of the electrodes and serves as the shell or container; (2) a carbon rod, which is the other electrode and extends through the center of the cell; and (3) an ammonium chloride paste, which is the electrolyte. The top of the cell is sealed to prevent evaporation of the moisture in the electrolyte, and the zinc shell is usually encased in steel or heavy paper. Proper care and intermittent use extends the life of this source of electrical energy.

In recent years the dry cell has been improved. One of these improvements is the so-called mercury cell. The negative electrode of this cell is made of an amalgam of powdered zinc and mercury, pressed into shape. The depolarizer is composed of mercuric oxide and graphite powder. The zinc-mercury amalgam cuts down local action, and the graphite helps reduce the internal resistance of the cell. Mercury cells have a considerably longer life than the ordinary zinc-carbon-ammonium chloride dry cell.

Scientific Principle Involved: Conversion of Energy

The dry cell produces an electric current by converting chemical energy into electrical energy. The conventional dry cell consists of a negative electrode (zinc case) and a positive electrode (carbon rod). Electrons must pass from the negative to the positive electrode (external circuit) before electrical energy is produced. A chemical substance (ammonium chloride) in the zinc container reacts with the zinc, forming zinc ions and liberating electrons. This reaction is very slight until the positive and negative electrodes are connected together in a circuit. When the circuit has been completed, the chemical reaction increases, and the electrons steadily move from the negative to the positive electrode through the external circuit. At this time hydrogen bubbles attempt to form a coating on the carbon electrode. Another chemical (manganese dioxide) is provided to dispose of these hydrogen bubbles in order that the chemical reaction may continue. The movement of electrons will continue until most of the zinc is consumed by the reaction.

1459

A cross-sectional view of a zinc-carbon-ammonium chloride dry cell shows the components (National Carbon Company, Inc.).

Application of Principle

1. Fresh dry cells and cells that are in various states of deterioration can be given an approximate test by connecting them in a circuit with a 1.5-volt light bulb and observing the intensity of the light. A more accurate test can be made with a battery tester which measures volts and amperes. Zinc-carbon cells, regardless of their size, deliver 1.5 volts. However, larger cells deliver more current. A fresh No. 6 dry cell delivers about 25 amperes, a penlight cell about three amperes. The ammeter test should be made only when necessary, and then as quickly as possible, because the drain of the current reduces the life of the cell. *Note:* Deteriorated cells are likely to expand or leak. They should be removed from flashlights and other devices. When dry-cell-powered equipment is stored, the batteries should be removed. A dry cell should be put into use before the expiration date that is stamped on the label.
2. The chemical action of a supposedly dead cell may be restored temporarily by punching a number of holes in the case and letting it stand in water for a short time. However, cells restored in this manner are of little practical use because they are only partially restored, their life is short, and they leak.
3. Dry cells in various states of deterioration may be displayed, attention being directed to swelling, perforation of the container, and corrosion. Cells may be cut in half to show their internal structure.

Unit 22 — STORAGE BATTERIES: SECONDARY CELLS

The storage battery is an electrochemical device for converting chemical energy into electrical energy. It consists of a number of storage cells connected in series. A storage cell is a secondary or voltaic cell that can be restored or recharged repeatedly. Storage cells of three types are now in general use: the lead-acid cell, the Edison cell, and the nickel-cadmium cell. The lead-acid storage cell, used in the batteries of automobiles, airplanes, trucks, motorcycles, and other equipment requiring a portable source of electrical energy, is by far the most widely used type. The electromotive force (emf) of each lead-acid cell is approximately 2.2 volts.

Lead-Acid Battery

Active materials within the lead-acid battery react chemically to produce direct current (DC) whenever lights, radio, starting (cranking) motor, or other current-consuming devices are connected to the battery circuit. This current is produced by the chemical reaction between the active materials of the plates and the sulfuric acid of the electrolyte.

14625

An interior-construction view of a typical 12-volt lead-acid storage battery illustrates internal cell connections (Delco-Remy Division, General Motors Corp.).

The battery performs three functions in automotive applications. First, it supplies electrical energy for the starting motor and for the ignition system as the engine is started. Second, it intermittently supplies current for the lights, radio, heater, and other accessories when the electrical demands of these devices exceed the output of the alternator. Third, the battery acts as a voltage stabilizer in the electrical system. Satisfactory operation of the vehicle is impossible unless the battery performs each of these functions.

The internal construction of a lead-acid storage battery is such that a highly reliable power source is provided. Two types of plates, one positive and the other negative, are the basic units. These plates consist of chemically active materials contained in grids. The grids are flat, rectangular, lattice-like castings. Each grid is designed specifically to hold the active materials. Once the grids have been pasted with the active materials, they are called plates. During the manufacturing process these plates are then said to be "charged." Charged negative plates contain sponge lead (Pb), which is gray in color. Charged positive plates contain lead peroxide (PbO_2), which has a dark brown color.

Safety Instructions

1. Obtain permission from your teacher before servicing or charging a storage battery.
2. Use proper instruments for testing a storage battery.
3. Avoid overfilling a battery, especially if it is to be charged.
4. Use water and baking soda (a neutralizer) to clean off the top of a battery.
5. Remove and transport a battery with a battery lifter.
6. Handle battery or acid with care. Wash immediately any part of your body or clothing that comes in contact with acid.
7. Wash hands immediately after handling a battery.
8. Wear goggles when using a charger.
9. Provide ample ventilation when using a charger.
10. Remove cell covers before charging a battery, unless the covers have other instructions upon them.
11. Keep open flames and sparks away from a battery being charged.

14626

12. Turn off charger before disconnecting leads (wires) from charger to battery.
13. Replace cell covers before moving battery.

Scientific Principle Involved: Conversion of Energy

Electromotive force (emf) can result from the immersion of certain pairs of dissimilar materials into the proper electrolyte. The lead-acid storage battery is a combination of negative plates of sponge lead (Pb) and positive plates of lead peroxide (PbO_2) immersed in an electrolyte of sulfuric acid (H_2SO_4) and water (H_2O). When the terminal posts are connected to form a complete circuit, a movement of electrons will result from the chemical action. This chemical reaction is between the active materials of two different kinds of plates and the electrolyte.

Each cell in a lead-acid storage battery has a potential of approximately 2 volts (actual potential is 2.2 volts per cell). Batteries containing three cells connected in series are 6-volt batteries; six cells connected in series are 12 volt. Applications requiring higher voltages use combinations of batteries, such as two 12-volt batteries connected in series to obtain a 24-volt system.

During the chemical reaction the oxygen (O_2) of the lead peroxide (PbO_2) of the positive plates combines with the hydrogen (H_2) of the sulfuric acid (H_2SO_4) to form water (H_2O); the sulfate (SO_4) from the sulfuric acid (H_2SO_4) combines with part of the lead (Pb) of the lead peroxide to form lead sulfate ($PbSO_4$). Also, a chemical change takes place at the negative plates. The lead (Pb) of the negative plate combines with the sulfate (SO_4) of the sulfuric acid (H_2SO_4) in the electrolyte to form lead sulfate ($PbSO_4$), which is the same material as the positive plates. The excess electrons transferred from the positive plates to the negative plates cause an imbalance which is corrected when the circuit is completed and the electrons move through the external circuit to the positive plates.

Application of Principle

1. A lead-acid cell can be made by placing parts of two plates (positive and negative) from a discarded storage battery in a dilute solution of sulfuric acid. When the plates are immersed in the electrolyte, little or no chemical action occurs. However, when the plates are connected in series with a 1.5-volt lamp, chemical activity will take place. *Note:* The use of an acid-resistant container of glass or plastic will make it possible to observe the chemical activity.
2. A simple voltaic cell can be made by inserting a strip of brass and a strip of galvanized iron (or a clean copper penny and a silver dime) into a lemon. Check current flow between strips or coins with a galvanomenter.

Electrolysis

Electrolysis is the decomposition of a chemical compound by means of electrical energy. Electrolysis has been put to many useful purposes in industry, such as in the manufacturing of chlorine and fluorine gases, in electroplating, and in the extracting of aluminum and certain other metals from their ores. However, electrolysis can occur where it is not desirable; for example, during the charging of a storage battery. If the rate during charging (amperage rate of current flow) is too high, the battery will heat, producing an excessive amount of explosive gas (a mixture of hydrogen and oxygen) by electrolysis. These gases are also produced when the battery is overcharged (when charging is continued after the battery has a full charge). When a storage battery is being charged, the manufacturer's recommended charging rate should be followed; the charging should be done in a well-ventilated area, away from heat, sparks, and open flame.

14627

Refer to the safety instructions previously mentioned in this unit.

Scientific Principle Involved:
Electrolysis

When an electrolytic cell (cell of a storage battery) is connected to a direct-current source, such as a battery charger, the cathode (negative plate) becomes negatively charged and the anode (positive plate) positively charged. Positive ions move to the cathode, where they acquire electrons from the cathode and are discharged. Negatively charged ions move to the anode and are discharged by giving up electrons to the anode. The loss of electrons by the cathode and the acquisition of a like number of electrons by the anode is, in effect, the conduction of electricity through the cell. The conduction of electricity through an electrolyte, together with the resulting chemical changes, is called electrolysis.

Application of Principle

The explosive nature of the hydrogen and oxygen gases produced through electrolysis when a storage battery is charged can be demonstrated by capturing the gases and igniting them in a safe manner. The demonstration can be conducted as follows:

1. A "cannon" can be constructed to demonstrate the potential hazard of a spark igniting gas given off from a storage battery being charged. An 18-inch length of 1½-inch pipe is capped at one end. The cap is drilled and tapped for a 14mm spark plug. This unit can be mounted on a stand. One terminal of a storage battery is connected by a length of No. 12 wire to a primary terminal of a 12-volt ignition coil and the cannon barrel (pipe). The other battery terminal is connected with No. 12 wire through a push-button starter switch to the other primary terminal of the ignition coil. The high-tension terminal is connected to the spark plug. Then the cannon barrel is placed for about five minutes over a cell opening of a battery that is charging and gassing freely. The cannon is then removed and placed at a demonstration location. The starter button is pressed to ignite the accumulated gas.

2. A simple means of capturing the gases produced during the charging of a storage battery is to insert in the cell openings of the battery rubber stoppers (with a hole in the center of each stopper for a glass elbow for the end cell and T joints for the others). The glass tubes are connected in series by the use of pieces of rubber tubing. This series hookup is then connected by a rubber tube that leads to a shallow pan partly filled with water. If all tubing connections are tight and the battery is charging, gas will bubble slowly from the submerged end of the tubing. After sufficient time has elapsed (ten minutes to half an hour) for the gases from the battery to replace the air in the tube, gas samples may be collected in small jars or wide-mouth bottles (2 to 8 ounces in capacity) by water displacement. So that the gas can be burned or exploded safely, the inverted jar is lifted from the pan, covered with a glass plate, and placed right side up on a table. At arm's length from the jar, the glass plate is removed and a burning match is thrust into the mouth of the jar. Pure hydrogen pops, then burns quietly with an almost invisible flame. Hydrogen mixed with oxygen or air explodes with a pop or a shriek, depending on the composition of the mixture. *Note:* Use only a small, wide-mouth bottle or jar for this demonstration. Do not collect gas in a large container and do not explode gas in a confined space, such as a bottle with a narrow neck or a bottle with a stopper. Do not attempt to light the gas at the end of the rubber tube.

Hydrometer Test

Each cell of a lead-acid storage battery contains balanced quantities of positive active material, negative active material, and sulfuric acid. The sulfuric acid is diluted with water, and the solution is called the electrolyte. When the cell is fully charged, the active materials are free of sulfate, and the strength of the electrolyte is at its maximum. When a cell discharges, the active materials react with the sulfuric acid in the electrolyte, and lead sulfate is formed on the plates. This reaction gradually lowers the strength of the electrolyte. Since the strength of the electrolyte varies directly with the state of the charge of the cell, this strength offers a convenient basis for estimating the state of the charge. To determine approximately the state of charge and how much energy is available from a battery, one needs only to measure the specific gravity of the electrolyte.

Specific gravity can be measured by means of a battery hydrometer. In the taking of a specific gravity reading, it is important that the float be freely suspended in the liquid, not touching the walls, top, or bottom of the barrel. It is important also that the eye be approximately at the liquid level when the reading is taken. Specific gravity readings are affected by temperatures; 80 degrees F. is the accepted standard. For every 10 degrees of electrolyte temperature *above* 80 degrees F., four gravity points (.004) must be *added* to the gravity reading. This addition compensates for the loss of gravity caused by expansion of the liquid as its temperature increases. For every 10 degrees of electrolyte temperature *below* 80 degrees F., four gravity points must be *subtracted* from the gravity reading. This subtraction compensates for the gain in gravity caused by the contraction of the liquid as its temperature decreases.

Refer to the safety instruction previously listed in this unit.

Scientific Principle Involved:
Specific Gravity

All liquids have weight; some weigh more than others. The weight of a unit volume (e.g., cubic centimeter) of a liquid is called its density. When the density of one liquid is compared to a standard, the relationship is called the liquid's specific gravity. All liquids are compared to water, which is given a specific gravity of 1.000. If it is found that 1 cubic centimeter of iron weighs 7.6 times as much as 1 cubic centimeter of water, it is said that the specific gravity of iron is 7.6. An object placed in a container of liquid is buoyed or lifted by an amount equal to the weight of the liquid it displaces; this is called Archimedes' principle. The denser the liquid, therefore, the greater is its buoyant force on the object. For example, as sulfuric acid is denser than water, a mixture containing more acid, as in a fully charged battery, will buoy a floating object higher than a mixture containing less acid, as in a discharged battery. A hydrometer uses a calibrated (specifically marked) float that measures the density or specific gravity of a liquid compared to pure water. Thus, this instrument will measure how much acid is mixed with the water in a battery by weighing the mixture – that is, more acid makes the float rise higher and less acid lets the float sink deeper. The markings on the calibrated float give the specific gravity of the mixture compared to pure water.

The hydrometer is used to measure the specific gravity of the storage battery electrolyte (Delco-Remy Division, General Motors Corp.).

Application of Principle

1. Information concerning the hydrometer can be applied by testing a storage battery (preferably one recently removed from an automobile). In the performance of the test, care

94629

must be taken to avoid spilling the electrolyte because it contains sulfuric acid, which can burn a person's skin or destroy his clothing. If spilling should occur, the acid should be washed off with plenty of water. The hands should always be washed immediately after a storage battery has been handled.

2. A hydrometer can be used to measure/test antifreeze solutions and crude oil.

Battery Installation and Servicing

A storage battery is designed to withstand normal operating conditions; however, excessive mechanical abuse will lead to early failure. Mechanical abuse often occurs during installation. So that a battery might be properly installed, recommendations for installation are given as follows:

1. Before installing the battery, check for proper battery polarity with respect to the vehicle's specifications. "Ground" polarity is usually indicated. Avoid reversed polarity during installation by marking cables as to their polarity when removing the old battery since reversed battery polarity may cause serious damage to the electrical system. Remember that the positive battery terminal post is larger than the negative terminal post. *Note:* When installing batteries, disconnect the "grounded" cable at the battery terminal first and reconnect it last to avoid damage to the battery and wiring by accidental "grounds."
2. Be sure that the battery carrier and hold-down device are clean and that the new battery rests level when installed.
3. Tighten the hold-down device until it is snug; however, do not draw it tight enough to distort or crack the battery case.
4. Be sure that the cables are in good condition and that the terminal clamps are clean.
5. Clean the battery terminals with a wire brush before attaching the cable clamps. Do not pound the clamps onto the battery terminals. When tightening cable nuts, use the wrench carefully to avoid twisting and damaging the cell cover.
6. Make sure that the cable terminals are clean and tight at the engine or frame and also at the cranking motor switch and solenoid.

The importance of periodic battery service cannot be overemphasized. With a reasonable amount of attention and care, the useful life of the battery can be greatly extended; neglect and abuse, however, will shorten its life. Any servicing and maintenance program should include the following points:

1. Inspect the battery thoroughly for defective cables, loose connectors, corrosion, cracked cases and covers, and loose hold-down devices.
2. Check the electrolyte level periodically, particularly in hot weather, and add pure water if necessary to bring the liquid to the required level in each cell. Overfilling should be avoided, as this will cause the loss of electrolyte, resulting in excessive corrosion, reduced battery performance, and shorter battery life. Allowing the electrolyte level to drop below the tops of the plates will cause the exposed plate material to become dry and chemically inactive. Also, the high concentration of electrolyte remaining in the battery will cause permanent damage on the plate area below the electrolyte level, causing poor battery performance and shorter life.

   If the battery requires the addition of an excessive amount of water in normal service, an overcharged condition is indicated. Some water usage is normal, usually 1 to 2 ounces per battery per 1,000 miles of service, depending on the type of service and prevailing temperatures. If the water usage becomes

14030

excessive, high battery temperatures or a high voltage-regulator setting should be suspected as the most likely causes. If very little water is used over three or four thousand miles of service, an undercharged battery may be indicated. Allowing the battery to remain in an undercharged condition for excessive periods may result in plate sulfation and permanent damage. The cause of the undercharged condition should be immediately corrected in order to insure optimum battery life.

3. Periodically, clean the battery top, posts, cable clamps, carrier, and hold-down device with a diluted ammonia or soda solution to remove corrosion and other foreign material. After cleaning, flush with clean water and apply a thin coating of petroleum jelly to the cable clamps and posts to retard corrosion. Tighten the hold-down device so that the battery will not shake in the carrier, but avoid over-tightening to avoid possible damage to the battery case.

Refer to the safety instructions previously listed in this unit.

Scientific Principle Involved:
Corrosion and Oxidation

The term corrosion may be used to denote the chemical change which takes place when a metal combines with oxygen. (Examples include the formation of an oxide scale on steel heated in air and of hydrous oxide rust on iron exposed to water or damp air.) Chemical change also occurs when metal comes into contact with an acid. The heat given off by an internal-combustion engine, moisture in the air, and the spilling or spraying of an electrolyte cause the corrosion of battery terminals, cable clamps, and holders.

Application of Principle

Skills can be applied and knowledge extended through the installation and servicing of storage batteries. Servicing can be made of batteries installed in automobiles or recently removed from them.

Selected References

Note: The numbers in parentheses in this section refer to entries in the list of selected references that appear within this publication immediately after the text.

(4), pp. 110-11; *(22)*, pp. 359-63; *(69)*, Chapter 19, pp. 13-14; *(71)*, p. 28; *(75)*, Chapter 36, pp. 19-24, *(78)*, pp. 247-57.

Battery Testing

The storage battery may be tested to determine if it is in good condition or if it is defective or worn out and must be replaced. Before the performance of any electrical checks, a visual inspection should be made to reveal any obvious defects. If the case or covers are cracked or if the battery has unusual odors or is otherwise damaged, the battery should be replaced.

The light-load test and the hydrometer test (which was explained earlier in this unit) should be performed on batteries having individual cell covers. The light-load test is simple, quick, and accurate; it should be applied to batteries before they are charged. Otherwise, defective cells may pass the test and cause a false diagnosis. An expanded scale voltmeter (one that has .01 volt per scale division) is needed for this test.

To check the electrical condition of battery cells using the light-load test, first check the electrolyte level in each cell. If necessary, raise it to the proper level by adding pure water. Then, if the battery is in the vehicle, place a load on the battery by holding the starter switch on for three seconds or until the engine starts. If the engine starts, turn off the ignition immediately. If the battery is out of the vehicle, place a 150-ampere load on it for three seconds. Next, turn on the headlights (low beam); or, if the battery is out of the vehicle, place a 10-ampere load on the battery. After one minute, with lights still on or the 10-ampere load still connected, read the voltage of each battery cell with a voltmeter, noting the exact voltages. It is necessary to remember only the highest and lowest cell voltages.

The condition of the battery can be determined by noting the difference in voltage readings between the individual cells as follows:

1. If any cell reads 1.95 volts or more and there is a difference of .05 volt (five divisions) or more between the highest and lowest cell, the battery is defective, damaged, or worn out and should be replaced.
2. If any cell reads 1.95 volts or more and the difference between the highest and lowest cell is less than .05 volt (five divisions), the battery is good and sufficiently charged.
3. If cells read both above and below 1.95 volts and the difference between the highest and lowest cell is less than .05 volt (five divisions), the battery is good but requires charging.

14631

If all cells read less than 1.95 volts, the battery state of charge is too low to test accurately. Boost-charge and repeat the light-load test. Boost-charge all 12-volt batteries rated at 100 ampere-hours or less at 50 amperes for 20 minutes (1,000 ampere-minutes). Charge all other batteries, both 6-and 12-volt, at 60 amperes for 30 minutes (1,800 ampere-minutes). If none of the cells comes up at 1.95 volts after the first boost charge, the battery should be given a second boost. Batteries which do not come up after a second boost charge should be replaced. If the charger being used will not give the rate specified, charge for an equal number of ampere-minutes at the next lower rate available. For purposes of the light-load test, do not boost a battery more than the amount indicated. If the battery is found to be good after boosting, it should be fully recharged by the slow-charge method before being placed in service.

The "421" test, the specific-gravity cell-comparison test, and the hydrometer test (which was explained earlier in this unit) may be used on batteries. In the specific-gravity cell-comparison test, the specific gravity of each cell, regardless of state of charge, is measured and interpreted. If specific gravity readings show a difference between the highest and lowest cell of .050 (50 points) or more, the battery is defective and must be replaced.

The "421" test is a specific, programmed test procedure consisting of a series of timed discharge and charge cycles that will determine the condition of the battery with a high degree of accuracy in a very short period of time. The "421" testers, which are manufactured by a number of different suppliers, automatically subject the battery to the programmed "421" test. The "421" testers, when used in the procedure as outlined in the chart that follows, will in two or three minutes accurately determine the condition of any 12-volt unit regardless of size, in or out of the vehicle, in any state of charge, and at any temperature.

EXAMINATION OR TEST	WHAT TO LOOK FOR	ACTION
1. VISUAL INSPECTION NOTE: If no visual defects are found proceed to Test 2.	a. Cracked cases and covers	REPLACE BATTERIES
	b. Electrolyte level below top of plates.	Low electrolyte level may cause permanent damage to batteries. Fill with water to proper level and proceed with careful testing of battery, to determine if damage has occurred. Low electrolyte level indicates that the battery has been neglected for an extended period of time and/or the battery is being subjected to overcharge in which case the charging system should be checked for correct voltage setting.
	c. Other abuse.	REPLACE BATTERIES—If terminals are loose or bent, sealing compound removed, cell covers damaged, plates or separators damaged by insertion of probes, tools, etc.
2. "421" TEST NOTES: A. *Do not charge units* prior to making test. B. "421" testers are produced by a number of different manufacturers—follow the directions for tester operation. C. Be certain to obtain clean and tight connections before performing this test. D. All meter readings must be made immediately after indicator light comes "ON"	Batteries designated as *Bad* by tester.	REPLACE BATTERIES
	Batteries designated as *Good* and with no owner complaint or indication of poor performance.	RETURN TO SERVICE— Posts, cables and top should be clean and batteries should be in at least a 75% state-of-charge.
	Batteries designated as *Good* by tester, but are still questionable because of owner complaint or age of battery.	Proceed to Step 3.
3. SPECIFIC GRAVITY (HYDROMETER) TEST NOTE: DO NOT charge battery prior to making test.	a. 50 points or more variation between highest and lowest cells.	REPLACE BATTERIES
	b. Less than 50 points variation between highest and lowest cells.	RETURN TO SERVICE— Posts, cables and top should be clean and the battery should be in at least 75% state-of-charge.

Refer to the safety instructions previously listed in this unit.

Scientific Principle Involved:
EMF and Capacity Rating

The lead-acid storage battery for automobiles with 6-volt electric systems is three 2.2-volt cells connected in series. The emf is approximately 6.6 volts. Six cells are connected in series to make up the battery for 12-volt systems.

The quantity of chemical energy stored in a battery depends on the magnitude (greatness) of the charging current and the time the current flows to bring it to a fully charged state. The capacity of a battery is usually rated in ampere-hours. One having a capacity rating of 90 ampere-hours could supply a current of 1 ampere for 90 hours, 2 amperes for 45 hours, 3 amperes for 30 hours, and so on.

Application of Principle

The procedures provided in this section can be used in testing storage batteries installed in vehicles or recently removed from them.

Selected References

Note: The numbers in parentheses in this section refer to entries in the list of selected references that appear within this publication immediately after the text.

(22), p. 204; *(26)*, pp. 298-99; *(27)*, pp. 469-72; *(33)*, p. 26; *(47)*, pp. 234-35; *(65)*, p. 198; *(86)*, pp. 46-47.

Battery Charging

There are two basic methods of recharging batteries. One is the slow-charge method and the other is the fast-charge method. As the names imply, the methods differ in the length of time the battery is charged and in the amount of charging current supplied. Before any battery is recharged, the cells should be checked and water added if necessary to bring the electrolyte to the proper level. Periodically during the charging process, the temperature of the electrolyte should be measured; and if the temperature exceeds 125 degrees F., the charge rate must be reduced or temporarily halted to avoid damage to the battery. The electrolyte temperature should never be allowed to exceed 125 degrees F.

The slow-charge method supplies the battery with a relatively low charging rate for a long period of time. The charging rate should be 7 percent of the ampere-hour rating of the battery. *Example:* If the ampere-hour rating is 60 a.h., the charge rate should be 4.2 amperes or, for all practical purposes, 4 amperes. If the ampere-hour rating of the battery is unknown, the charge rate should be 5 amperes for passenger-car type batteries and 9 amperes for heavier batteries. Charging periods of 24 hours and more may be needed to bring the battery to full charge. The battery is fully charged when the cells are gassing freely and no change in specific gravity occurs over a one-hour period. Sulfated batteries (that is, batteries which have stood in a discharged condition for long periods of time without recharging) may require three or four days of slow charging in order to bring the battery to a fully charged condition. Batteries which are permanently sulfated can never be restored to a normal operating condition, regardless of the rate of charge or the length of time the charge is applied.

The fast-charge method supplies the battery with a high charging rate for a short period of time. Charging rates of 40 to 70 amperes are common, with charge periods varying from 1½ to 3 hours, depending on battery type and size. The high charging rate may be continued for as long as there is no electrolyte loss and the electrolyte temperature does not exceed 125 degrees F. Because of the short charging period and the high charging rate, the plates are not fully converted to lead peroxide (PbO_2) and sponge lead (Pb). This deficiency means that a battery cannot be fully recharged by the fast-charge method although it can be substantially "boosted" or recharged. For the complete recharging of the battery, the fast-charge procedure should be followed with a slow charge for a few hours. When fast chargers are used, the safeguards built into the charger by the manufacturer should never be ignored or circumvented as these safeguards are intended to protect the battery from damage. It is important to remember that an explosive mixture of hydrogen and oxygen gases is formed when any battery is being charged. As the mixture escapes through the battery vents, normal air circulation usually carries the explosive mixture away. But if circulation is poor or if the battery is being heavily charged, the explosive mixture may accumulate near the battery. Since a spark or flame can ignite the mixture and cause an internal battery explosion, care should be taken to avoid sparks and flame near the battery.

Refer to the safety instructions previously listed in this unit.

94633

Scientific Principle Involved: Chemical Change

The sulfuric acid electrolyte contains both hydrogen ions (H+) and sulfate ions (SO_4-). The negative plate, which is sponge lead, reacts with the sulfate ions in the electrolyte to produce a deposit of lead sulfate. During this reaction electrons are released; they move through the external circuit to provide electric power for the starter, lights, and other electrical equipment of the internal-combustion engine unit. The lead peroxide of the positive plate reacts with the hydrogen and sulfate ions of the electrolyte to form water and a deposit of lead sulfate.

When the external circuit is open, the movement of electrons is interrupted, causing both chemical reactions to stop. If the circuit is closed for a long period of time without the benefit of a charging current, the reactions will continue until the plate surfaces are covered with lead sulfate and most of the hydrogen and sulfate ions are removed from the electrolyte. The sponge lead of the negative plate and the porous lead peroxide of the positive plate provide greater internal surface areas for chemical change and collection of the lead-sulfate deposit.

Certain chemical reactions that produce a movement of electrons can be reversed if the movement of electrons is reversed. All rechargeable cells depend on a reaction of this type. When a lead and sulfuric acid battery is connected to a charger, the reactions are reversed. When charging is complete, both plates are restored to their original composition, and the electrolyte is restored to its original concentration of sulfuric acid (hydrogen and sulfate ions). This process is illustrated in a formula as follows:

$$PbO_2 + Pb + 2H_2SO_4 \underset{\text{Charging}}{\overset{\text{Discharging}}{\rightleftharpoons}} 2PbSO_4 + 2H_2O$$

Application of Principle

Charge lead-acid storage batteries and make tests covered under "Hydrometer Test" and "Battery Testing" in this unit.

Unit 23 — GENERATION OF ELECTRICITY

This unit deals with (1) magnetos; (2) direct-current generators and alternators; (3) alternating-current rectifiers; and (4) generator regulation.

Magnetos

A magneto is a device which generates and distributes electricity for igniting the compressed fuel-air mixture in the combustion chamber of internal-combustion engines used to operate vehicles and portable or stationary equipment (for example, lawn mowers, motorcycles, chain saws, portable lighting systems, and outboard motorboats).

The magneto generates the electricity, steps up the low voltage to a high-tension voltage, and distributes it to the cylinder (or cylinders) at the correct instant. These operations are done without the aid of a storage battery. Certain magnetos are low-tension types; they generate a low voltage, which is then stepped up to a high voltage by means of a separate coil. High-tension magnetos produce voltage of sufficient value to jump the spark-plug gap without the use of a separate coil.

The difference between a magneto and a generator is that while the generator has an electromagnetic field requiring an outside source of electricity to excite it, the magneto uses permanent magnets for this field. Magneto ignition systems have certain advantages over the battery-demanding systems. The magneto systems are more portable and lighter, and they provide a spark that is hotter as the engine speed increases.

There are two types of magnetos, the low-tension type and the high-tension type. Magnetos are classified further according to the part of the magneto which is revolved. A magneto that has its windings on a rotor which is revolved in a magnetic field is known as a shuttle-wound magneto. In the

The magneto of a small engine produces electricity when the flywheel is rotated by the pulling of a rope wound around a pulley attached to the crankshaft (Briggs and Stratton Corp.).

inductor-type magneto both the coil and the magnet are mounted in stationary positions; movement of the magnetic field is obtained by making and breaking the magnetic field. A newly developed magneto, known as a revolving magnetic design, has been made possible by new types of magnets. The coil of the magneto is mounted in a stationary position, and one or more magnets are revolved between the pole pieces of the magneto.

A magneto, in a sense, consists of two simple circuits; one is called a primary circuit and the other a secondary circuit. Both circuits have windings which surround the same iron core, and the magnets in the flywheel or rotor act on both circuits. Current can be induced in each circuit by changing the magnetism in or around the coils. The primary circuit, which has relatively few turns of heavy wire, includes a set of breaker points and a capacitor. The secondary circuit, which has a coil with many turns of lighter wire wound around the outside of the primary winding, includes a spark plug. A permanent magnet is mounted in the flywheel or rotor; as the flywheel rotates, the magnet is brought into proximity with the coil and core.

Scientific Principle Involved:
Magnetism

Every magnet has a north pole and a south pole. Like poles repel each other (two north poles or two south poles); unlike poles attract each other (a north pole and a south pole). The reason for this phenomenon is that a magnetic force (or field) exists between the opposite poles of a magnet. This magnetic field is composed of invisible lines of force (magnetic flux).

There are two types of magnets, permanent magnets and temporary magnets (electromagnets). The earliest type of permanent magnet was the natural one of ore and was used as a compass in navigation. It was called a lodestone (lead stone). Now, permanent magnets are manufactured. Two common shapes of manufactured magnets are the bar magnet, which has a pole at each end, and the horseshoe magnet, which is a bar magnet that has been bent into a **U** shape so that the poles are close together. Originally, manufactured magnets were made of high carbon steel. Now, high quality permanent magnets are manufactured from alloys of steel and tungsten, chromium, and cobalt; from alloys of nickel and chromium; and from ceramics. These magnets not only are stronger but retain their magnetism for much longer periods.

The movement of electrons (flow of current) can be caused by revolving a coil of wire in a

The schematic diagram given above presents the components of a flywheel-type magneto used in an outboard motor (Evinrude Motors).

magnetic field. In a conventional generator the magnetic field is produced by passing current through the field coils, which in turn produce the magnetic field (electromagnets). In the case of the magneto, the magnetic field is produced by means of permanent magnets. Magneto ignition systems

14635

A flywheel magneto provides electrical current needed to operate the engine and the electrical components shown in the motor-scooter wiring diagram (Lambretta: Innocenti Motor Division).

have distinct advantages. They do not require any storage battery or other source of current, and the intensity of the generated voltage does not decrease but increases with the engine speed. Magnetos are particularly popular for internal-combusion engines where a storage battery is not needed for starting or lighting. The recent development of permanent magnets of greatly increased strength has improved their performance.

Application of Principle

1. Place a magnet under a sheet of glass or a piece of cardboard. Sprinkle iron filings on the glass or cardboard and tap lightly. The iron filings will show the form of the magnetic field.
2. Locate permanent magnets used in the components of small engines and automobiles (magneto, radio speaker, and compass).
3. Check the permanent magnet in a speedometer.
4. Service or repair a magneto.

Direct-Current Generators and Alternators

The automobile must have some source of direct current (DC) to operate the starter, ignition, lights, and electrically operated accessories. A storage battery will furnish this electrical energy for a limited time. A direct-current generator, which converts mechanical energy provided by the engine to electrical energy, has been used for a number of years to keep the battery charged. Demands of the electrical system of modern automobiles have placed a heavy strain on the generator. For this reason the direct-current generator has been replaced in many vehicles by the alternator (alternating-current generator), which has the advantage of producing current at low speeds even when the

14636

engine idles or the car is moving through slow traffic. The alternator produces alternating current (AC) much like that available in home electrical circuits. A rectifier is used to convert this alternating current to direct current. Manufacturers' directions should be followed when direct-current generators and alternators are installed and tested.

Scientific Principle Involved: Electromagnetic Induction

An electric potential is produced when a coil of wire is passed through a magnetic field. This principle is used in the automobile generator to produce current. When the armature (rotor) of a generator is turning, the coils pass through the magnetic flux of the field coils, producing an alternating current in the coils of the armature. The current alternates because the armature coil approaches the magnetic field from one direction and leaves in another. This movement causes the current to flow first in one direction and then in another, thus producing alternating current. The direct-current generator uses a commutator made of segments arranged on the armature so that they contact the brushes at the proper times during the rotation. This contact causes the pulsating current to flow in only one direction in the external circuit. The alternator uses slip rings and collects the alternating current, which is then converted to direct current with a rectifier. Unlike the magneto, which uses permanent magnets, these generators use field coils, which are electromagnets (temporary magnets). The electromagnets produce the

A basic direct-current generator is identical to a basic alternating-current generator except that one has a commutator and the other has slip rings. If the commutator (1) is replaced by the slip rings (2), the generator's output will become alternating current instead of direct current.

The illustrations presented above give an end view and a sectional view of a direct-current passenger-car generator (Delco-Remy Division, General Motors Corp.).

14637

The illustrations presented above give an end view and a sectional view of an alternating-current generator (alternator) (Delco-Remy Division, General Motors Corp.).

properly oriented magnetic field when direct current is sent through the field coils as part of the direct current produced by the generator is supplied to these coils.

Application of Principle

1. The relationship of the field strength to the generator output can be shown by placing a variable resistor in the field circuit and regulating the amount of direct current supplied to the field.
2. A generator can be designed, constructed, and operated by a group of students.
3. Generators can be checked, serviced, and repaired.
4. A 6- or 12-volt light bulb can be connected to each end of a generator field coil; when the coil is lowered into the field of an operating growler, the bulb will light up.

The rotor-type alternating-current generator used in motorcycles is composed of a stator with coils which are wound around iron cores and a rotor made of permanent magnets which is attached to the crankshaft (Honda Motor Company, Ltd.).

Alternating-Current Rectifiers

Alternating-current generators (alternators) produce alternating current that is used in the home, in industry, and in the electrical components of automobiles and other units driven by internal-combustion engines. However, direct current is required for the operation of certain components of many electric/electronic devices, such as the electrical systems of internal-combustion-engine units, the circuits of radio and television transmitters and receivers, and measuring instruments (meters). Therefore, the alternating-current output of alternating-current generators must at times be changed or rectified to direct current. This change or rectification is accomplished by the use of selenium, silicon, magnesium-copper sulphide, or copper-oxide rectifiers or electron tubes, which furnish a one-way path for electric current or movement of electrons.

The silicon rectifier or silicon diode rectifier is one of the most recent types of rectifiers to be developed. Because of its small size, it is built into the frame of the automobile's alternator. Plate-type rectifiers are relatively large in size and are mounted externally.

Single-phase alternating current would result in a pulsating current. To provide a much smoother flow of current, alternators are built with three stator circuits which, in effect, give overlapping pulses of alternating current. When these pulses are rectified through diodes, a comparatively smooth flow of direct current is obtained.

A full-wave or bridge rectifier is used to rectify alternating current produced by alternators. In the diagram presented above, four selenium rectifiers are interconnected to provide direct current during both halves of the alternating-current cycle (Honda Motor Company, Ltd.).

Scientific Principle Involved: Rectification

The process of changing alternating current to direct current is called rectification. When a silicon diode rectifier is placed in series with a load (electrical device) in a circuit and is supplied with an alternating current, the current is allowed to flow in only one direction. This type of rectifier, which is called a half-wave rectifier, provides pulsating direct current. For one half of each cycle of alternating current, the current flows through the rectifier and load. During the other half-cycle, the current cannot flow through the rectifier so that no current flows through the circuit. Capacitors can be used to smooth out the pulsating current; however, full-wave or bridge rectifiers, which use both halves of each cycle, or three-phase alternators produce a smoother direct-current output.

In the diagram of a single-phase alternating current (1), the positive half wave is represented by (a), the negative half wave by (b). In the three-phase alternating current (2), the phase outputs overlap but do not coincide. The three-phase alternating current depicted in (2) is shown as rectified direct current in (3).

14639

Application of Principle

1. Locate rectifiers in the generator circuit of automobiles and other units driven by internal-combustion engines.
2. Disassemble, clean, check, and, if necessary, repair generators used in the electrical system of internal-combustion-engine units.
3. Mount a ½-horsepower, single-phase motor, a 35-ampere alternator, a regulator, and a storage battery on a piece of plywood. Charge the battery by driving the alternator with the motor.
4. Use an ohmmeter to demonstrate how a silicon diode rectifier will have low resistance in one direction and high resistance in the other.
5. Demonstrate magnetic fields by placing several coils around a cardboard tube and pulling a piece of iron through the tube by turning on each coil in turn.

Generator Regulation

Both alternating-current and direct-current generators require a regulator which prevents the generator from producing excessive voltage/current. Without regulation, a generator would continue to increase its output as speed increased until it would be producing so much current that it would overheat and burn up. If an unregulated generator were connected to the electric circuit of an automobile or to other units driven by an internal-combustion engine, the storage battery would be greatly overcharged and the electrical devices could be damaged. The direct-current generator uses an external resistance to control voltage and amperage output. Various devices are used to regulate alternating-current generators by placing resistance in the generator field circuit. Cutout relays (circuit breakers) are a part of the regulation system of direct-current generators and some alternating-current generators. The cutout relay closes the circuit between the generator and battery when the generator is producing current; it opens this circuit so that the battery cannot discharge through the generator when the generator slows or stops. Certain alternating-current generators, because their design makes them self-limiting, have no cutout relays and no current regulators. The rectifying diodes or transistors in the circuit (transistor systems) prevent reverse current or discharge of the battery through the generator.

A conventional three-unit regulator is used with a generator.

Scientific Principle Involved: Electromagnetic Switch

The cutout relay, voltage regulator, and current regulator are switches operated by an electromagnet. The cutout relay consists of two windings (coils) around a core and a flat steel armature, mounted on a hinge above the core. A contact point on the armature is positioned just above a stationary contact point that is connected to the battery. When the generator is not operating, a spring holds the two points apart, keeping open the circuit between the generator and battery. When the generator begins to operate, current flows through one winding, induces voltage in the other winding, and creates a magnetic field around the core. The armature is pulled by the electromagnet and the contact points come together (close). This action completes the circuit between the generator and the battery. When the generator stops, current begins to flow from the battery to the generator.

14640

This reversal of current flow creates a reverse magnetic field in one winding which bucks the magnetic field in the other winding. The weakened magnetic field can no longer hold the armature down and keep the contact points together. When the armature springs up, the circuit between the battery and the generator opens.

The alternator employs a transistor regulator.

Application of Principle

1. Locate regulators in the generator circuit of automobiles and other units driven by internal-combustion engines.
2. Clean, check, and, if necessary, repair regulators (cutout relays, voltage regulators, current regulators, and transistor systems).

Unit 24 — TRANSMISSION OF ELECTRIC POWER

Both the storage battery and the electric generator (alternator) have positive and negative terminals. The positive terminal, which has a shortage of electrons, attracts electrons. The negative terminal, which has an excess of electrons, repels electrons. When a circuit is completed between the terminals, electrons move through the circuit. They will move as long as there is a complete circuit and as long as the electromotive force is maintained. The original electrons that start out displace electrons in the next atoms, and so on along the length of the circuit. The movement of electrons is called an electric current.

The modern automobile has an alternator and a storage battery to supply the electrical system. Electrons move (or current flows) through wires to the ignition and lighting systems and through cables to the storage battery and the starting (cranking) motor. The internal current flow in the electrolyte is a movement of positive and negative ions in opposite directions.

Scientific Principle Involved:
Electromotive Force

A device such as a storage battery or an electric generator provides the electromotive force which removes electrons from one end of a wire and piles them up at the other end. When the number of electrons at one end of a wire exceeds the number at the other end, an electric field is set up between the ends of the wire. This field causes free electrons in the wire to move from the negative end to the positive one. This movement of electrons is the flow of electric current; it is the electromotive force (voltage) that creates the electric pressure that causes the current to flow.

Application of Principle

1. Use a proper meter to check the electromotive force (voltage) of a storage battery and a generator.
2. Use a proper meter to determine the positive and negative terminals of a dry cell and a storage battery.

Note: An ammeter must always be connected in series with the circuit. To make a series connection requires breaking the circuit to connect the meter. A voltmeter is always connected in parallel or across the circuit. The circuit does not have to be broken so that voltage can be measured. Use direct-current meters to measure direct currents and voltages. Direct-current meters must always be connected with the correct polarity. Use alternat-

DAPI 14641

ing-current meters to measure alternating currents and voltages.

Conductors and Insulators

A conductor is a material that readily allows a flow of electrical current (movement of electrons). Metals are good conductors of electricity. Silver is the best conductor; copper and aluminum follow, in that order. For this reason wires, cables, straps, and bars used in transmitting electric power are made of copper or aluminum, and silver is used in the manufacture of many electronic parts. Solutions of salts, acids, and bases are fairly good conductors.

An insulator is a material that will not readily conduct electricity (resisting the movement of electrons). Rubber, glass, porcelain, mica, amber, oils, and sulfur are good insulators. Rubber and plastic serve as insulating shields around wires used to conduct electricity. Power lines are attached to insulators made of glass or porcelain. Pure water is an insulator, but water from a faucet is not because it usually contains small amounts of dissolved impurities.

The movement of electrons can be stopped by an open circuit (a switch in the "off" position or a break in a conductor) or shorted or grounded by a conductor that is not a part of the intended circuit.

Scientific Principle Involved: Electron Theory

An atom is composed of particles of matter called protons, neutrons, and electrons. The protons and neutrons form the nucleus, which is the center of the atom. The electrons are arranged outside the nucleus in an orderly manner. Each atom has an equal number of protons and electrons. The proton carries a positive (+) electric charge, the neutron carries no electric charge, and the electron carries a negative (–) electric charge. A normal atom has no electric charge because the positive charge of the protons in the nucleus is canceled or neutralized by the negative charge of the electrons outside the nucleus.

The protons in the nucleus cannot easily be moved; however, the electrons can be disturbed and even pulled away from the atom. When this occurs and electrons are taken away from a neutral atom, the atom has a positive charge and becomes a positive ion; that is, the atom has more positively charged protons than negatively charged electrons. Conversely, if extra electrons are added to a neutral atom, the atom has a negative charge and becomes a negative ion.

Some atoms hold their electrons very tightly. Substances made up of atoms of this type are known as insulators; electrons do not move through them easily. These substances are usually nonmetallic. Other atoms have electrons that are held very loosely. Some of these electrons jump rapidly from atom to atom as "free electrons." Substances made up of atoms of this type are called conductors; electrons move through them easily. The best conductors are metals, such as silver, copper, and aluminum. When electrons are taken from atoms in a conductor, the atoms become charged positively, and the electrons from nearby atoms are attracted to them, moving into spaces left by the departed electrons. This action is repeated along the entire length of the conductor. A positive charge placed on any part of the conductor causes a movement of electrons from atom to atom within the conductor. This movement of electrons is called an electrical current.

Application of Principle

1. Check the amperage of circuits using an ammeter, a 1.5-volt dry cell, and the types and lengths of wires that follow:
   a. Five feet each of No. 22 copper, aluminum, and nichrome wire, connected separately in circuits

b. Five feet of No. 18 copper wire, and then five feet of No. 28 copper wire
c. One foot of No. 28 copper wire and then a ten-foot piece of No. 28 copper wire

2. Attempt to operate the starting (cranking) motor of an automobile by connecting a small gauge conductor, such as a length of No. 16 copper wire, between storage battery and starter.
3. Inspect the electrical systems of a small engine unit and an automobile.

Voltage, Current, and Resistance

Voltage (E) or electromotive force (emf) is electrical pressure that will cause electrons to move (current to flow) in a closed circuit. The force is the repelling force caused by a surplus of electrons and the attracting force caused by a deficiency of electrons. Electrical pressure or potential difference is measured in volts. It is the voltage which causes the flow of current in a closed circuit to provide heat and light and operate electrical equipment.

Current (I) is the rate of the electron movement. Current may be simply described as the rate of movement of electrons in a circuit. The basic unit of measurement for current is the ampere. Electrons move from negative to positive in a circuit.

Resistance (R) is opposition to the movement of electrons (flow of current) and is measured in ohms. All components in a circuit, including wires, have some resistance. Electric motors, appliances, and other electrical devices have resistance. Resistance is the property limiting the flow of current in a closed circuit.

Scientific Principle Involved: Ohm's Law

The movement of electrons in an electrical circuit occurs when voltage overcomes resistance, causing current to flow. Voltage is the pressure that causes the flow of current (movement of electrons). Resistance is the opposition offered by the circuit to the flow of current (movement of electrons). Current is the movement of electrons. Ohm's law states the relationship of voltage, current, and resistance as follows: *Voltage = current × resistance.*

Ohm's law plays an important role in the checking of automotive and other electric circuits. When electric meters are used to measure the voltage, current, and resistance in a circuit, Ohm's law is applied. Voltage is measured in volts, current in amperes (amps), and resistance in ohms. The symbols or letters used to represent voltage, current, and resistance are E for voltage, I for current, and R for resistance. The relationship *Voltage = current × resistance* can also be expressed as $E = I \times R$. When the voltage and resistance are known, the amount of current is found by using $I = E \div R$; when the voltage and current are known, the resistance is found by using $R = E \div I$. Some practical examples are given as follows:

1. A headlight has a resistance of 4 ohms. When it is connected to a 12-volt battery, how much current will it draw?

   $I = E \div R; I = 12 \div 4; I = 3$ *amperes*

2. A 12-volt battery delivers 100 amperes to a starting motor. What is the total resistance of the starting circuit?

   $R = E \div I; R = 12 \div 100; R = .12$ *ohms*

3. A poorly connected battery cable has a resistance of 1 ohm. How much voltage will be required to push 300 amperes through this bad connection?

   $E = I \times R; E = 300 \times 1; E = 300$ *volts*

Application of Principle

1. Voltmeters, ammeters, and ohmmeters can be used to measure electrical conditions in circuits. An ohmmeter is used to measure the resistance of an open circuit. A voltmeter is used to measure the voltage drop between two points in a closed circuit and the total circuit voltage. An ammeter is used to measure current flow in a closed circuit.
2. A proper meter should be used to determine sources of resistance in the starting circuit of an automobile, including (a) corroded terminals; (b) broken insulation; and (c) frayed or broken wires.

14643

3. Determine the resistances of resistors by reading the color codes and checking with an ohmmeter.

Series and Parallel Circuits

Electrons move (current flows) from a high-potential point (excess of electrons) to a low-potential point (deficiency of electrons). The path or paths followed by the electrons or current is called the electric circuit. All circuits must contain a source of electromotive force to bring about the difference of potential that causes electrons to move (current to flow). This source may be an electric cell, a mechanical generator, or another device that provides electric power. All paths of the circuit lead from the high-potential (negative) end of the electromotive source to its low-potential (positive) end.

The electrons (or current) in a circuit follow paths provided by solid conductors, liquids, gases, vacuums, or any combinations of these. Its path may include electric lights, heaters, motors, or any other of the many devices requiring electricity.

The three general types of electric circuits are (1) the series circuit, which provides a single, continuous path for electrons to move (current to flow) from the negative side of the electromotive-force source to the positive side; (2) the parallel circuit, which provides two or more parallel paths for electron movement (current flow) from negative to positive; and (3) the series-parallel circuit, a combination of the other two.

Scientific Principle Involved: Direct-Current Circuit

In a series circuit the current flow is the same in all parts of the circuit; the total resistance is equal to the sum of the individual resistances; and voltage is equal to the sum of the potential differences across each of the individual resistances. In a parallel circuit the voltage is the same across all resistances; the total current is equal to the sum of the currents through its branches; and the total resistance is equal to the voltage across the resistances divided by the total current in the circuit.

Electrons move from the negative side of the power source (EMF) through the resistances and back to the positive side of the source. In the series circuit the electrons move through resistors R^1 and R^2 (load); in the parallel circuit, through R^1 and R^2; and in the series-parallel circuit, through R^1 (in series) and then through R^2 and R^3 (in parallel).

Application of Principle

1. Trace, check, and measure circuits in electrical systems and devices.
2. Hook up series, parallel, and series-parallel circuits by using lengths of wire and light bulbs or other resistances to prove the relationships between voltage, current, and resistance in these circuits.

14644

Unit 25 — TRANSFORMERS

Transformers are most often used where electrical voltage needs to be either increased or decreased. Power transformers used to increase or decrease voltage are classified as step-up or step-down transformers. A very common application of a step-down transformer can be found in the model train transformer or the doorbell transformer, where the 120-volt alternating current used in home electrical circuits is reduced from 8 to 24 volts. An example of a step-up transformer used to increase voltage is the transformer connected to a neon sign which will increase 120 volts to the several thousand volts necessary for the operation of the sign. Many electronic devices, such as radios, stereos, tape recorders, and television sets, use power transformers to increase or decrease voltage to the desired amounts.

Power transformers consist of two or more coils of wire wound around a laminated metal core. The winding carrying the current from the source of electrical power is called the primary winding. The other winding or windings which carry the induced voltage are called secondary windings. A transformer may have one or more secondary coils which step up or step down the voltage.

The two leads of the primary winding are connected to the source of power, which must be an alternating current or an interrupted direct current. The current through the secondary coil or coils is known as the induced current, and its voltage is known as the induced voltage. If the number of turns of wire in the secondary coil equals the number of turns in the primary coil, the induced voltage will be the same as the voltage applied to the primary coil. If the number of turns in the secondary coil is less than the number in the primary coil, the voltage will be reduced; and if the number of turns in the secondary coil is greater than the number in the primary coil, the voltage will be increased. Thus, the ratio of the voltage induced in the secondary coil or coils to the voltage applied to the primary coil is the same as the ratio of the number of turns of wire in the secondary coil to the number in the primary coil.

Scientific Principle Involved: Electromagnetic Induction

An electric current flowing in a wire produces a magnetic field around the wire; the greater the movement of electrons, the greater is the strength of the magnetic field. A coil of insulated wire carrying an electric current becomes an electromagnet whose strength is determined in direct proportion to the amount of current and the number of turns of wire in the coil. Using a permeable steel core also greatly increases the strength of the electromagnet because the core itself becomes a strong temporary magnet. Reversing the movement of electrons in the coil reverses the magnetic field of the coil.

Moving a magnet perpendicular to a wire produces the movement of electrons along the wire. Moving a magnetic field through a coil of wire induces an electromotive force in the coil. The strength of the electromotive force is in direct proportion to the rate of change of the magnetic field and to the number of turns of the coil. Reversing the magnetic field reverses the direction of the induced voltage.

In a power transformer the changing magnetic field that is produced by the alternating current in the primary induces an alternating electromotive force of the same frequency in the secondary. Since the rate of change of magnetic flux is the same for both the primary and secondary windings, the voltage ratio is the same as the ratio of turns of wire in the coils.

The step-up transformer (left) and the step-down transformer (right) show the direct relationship of the number of turns of the coils to the voltage.

14345

In an ignition coil of an automobile, the voltage (6 or 12 volts) of the storage battery is transformed or stepped up to the high voltage required to make the current jump the spark-plug gap. The ignition coil has a primary circuit made up of a winding of a few hundred turns of relatively heavy wire and a secondary circuit made up of a winding of many thousands of turns of fine wire. When the distributor contact points close and current flows in the primary circuit, a magnetic field builds up. When the distributor contact points open and the current stops flowing, the magnetic field collapses. The collapsing magnetic field induces high voltage in the secondary winding. This induction creates the high-voltage surge that is conducted through the distributor rotor and cap to a spark plug.

The increase in voltage in the step-up transformer and the automobile ignition coil is accompanied by a corresponding decrease in current so that the power output (volts X amperes) cannot be greater than the power input. These devices are highly efficient (95 percent or better) since losses of energy are relatively small in the form of heat due to resistance of the windings, eddy currents, and hysteresis in the laminated and highly permeable core.

Application of Principle

1. Electromagnetic induction can be demonstrated by connecting a coil of wire to a galvanometer and moving a permanent magnet past or through the coil of wire. Induced voltage increases as the speed of the magnet is increased, and the direction of current flow (indicated by the deflection of the needle) changes as the direction of the magnet is changed.
2. A graphic illustration of how an electromagnet will develop a magnetic field can be obtained by connecting the ignition coil of an automobile to a battery and the high tension lead to a spark plug. A spark appears at the spark-plug gap as the flow of electricity is interrupted. An automotive ignition capacitor placed across the switch changes the spark as it arcs the gap. This change demonstrates an increase in voltage.
3. The following procedure can be used to illustrate a decrease in voltage: first, connect a doorbell transformer to the ordinary 120-volt house current; then connect a voltmeter across the output terminals and observe the voltage, which should be approximately 15 volts (depending on the specific transformer used).

Unit 26 — SPARK PLUGS

Spark plugs, which produce high-voltage sparks to ignite combustible fuel mixtures, are found in devices such as furnaces, heating units of steam cleaners, and internal-combustion engines. The spark plug consists of a steel shell in which is fastened a porcelain insulator. (An insulator is a nonconductor, a material through which electricity will not pass.) An electrode runs through the center of this insulator and another electrode extends out from the bottom of the steel shell to a position close to the center electrode. When the spark plug is used in the ignition system of an automobile, the shell is screwed into the cylinder head, and the wire from the distributor is connected to the top of the center electrode. The electricity (the voltage boosted by the coil) travels down the center electode and jumps the gap to the other electrode. Then it travels to the engine block and back to the coil through "ground." The fuel mixture is ignited when the electric spark jumps the gap between the electrodes at the proper time near the end of the compression stroke.

Spark plugs are classified according to a heat range which indicates their ability to transfer heat from the firing tip of the insulator to the cooling system of the engine. The rate of heat transfer is controlled basically by the distance the heat must travel to reach the cooling medium. A "cold" plug, which has a relatively short insulator nose, transfers heat very rapidly into the engine's cooling

14646

system. Such a plug is used in heavy-duty or continuous, high-speed operation to avoid overheating. A "hot" plug, which has a much longer insulator nose, transfers heat more slowly away from its firing end. Thus it runs hotter and burns off combustion deposits which might tend to foul the plug during prolonged idle or low speed operation. Because the operating temperatures of spark plugs vary in different engines and under different engine service conditions, the plugs are made in several heat ranges.

Scientific Principle Involved: Ionization of Gases

Dry air at atmospheric or higher pressures is such a poor conductor of electricity that it can for practical purposes be considered an insulator for low voltages. The atoms that compose the molecules of any gas occasionally lose an electron and become positive ions. Thus, there are always a few positive ions and free electrons present in the air. A higher percentage of these electrically charged particles is normally present in heated gases, such as the compressed fuel-air mixture in the combustion chamber of a gasoline engine. The high voltage of the ignition coil produces strong electrical forces on the electrically charged particles in the gap between the electrodes. Free electrons accelerating rapidly toward the positive electrode collide with molecules of the gases, causing further ionization and a movement of electrons across the gap. Rapid interactions among the ions and molecules of the gases result in the release of heat, light, and sound energy in a spark discharge similar, but on a smaller scale, to the discharge of lightning between a cloud and the earth. This energy released in the gap of the spark plug is sufficient to ignite the fuel-air mixture in the combusion chamber.

Application of Principle

Compare the test results obtained on a spark plug cleaning and testing machine, using a new and a used spark plug. Remove, test, clean, and reinstall spark plugs according to the procedures that follow:

1. Loosen the plugs for one or two turns with a spark-plug wrench or a deep-socket wrench.
2. Blow the dirt out of spark-plug ports.
3. Remove the plugs the rest of the way, keeping them in their respective order.
4. Analyze visually the condition of the spark plug (normal, oil-fouled, too hot, too cold).
5. Clean the exterior of the plugs in solvent to remove grease and dirt. Allow to dry.
6. Clean with the spark plug cleaning machine.
7. Open the spark-plug electrode gap and file the electrodes to obtain clean, bright sparking surfaces.
8. Reset the spark-plug gap to proper specifications, using the wire-type gauge and bending the side electrode only.
9. Use a spark plug cleaning and testing machine. Compare sparking efficiency with a new plug.
10. Place the spark plugs (with new gaskets) back in the engine, tightening them to the recommended torque.

It is essential that the spark plugs be the right type for the engine in which they are used (Champion Spark Plug Company, Toledo, Ohio).

Unit 27 — IGNITION SYSTEMS

The purpose of the ignition system is to develop and deliver high-voltage electricity so that the spark plugs in the engine cylinders can deliver a high-voltage spark to ignite the air and gasoline mixture at the proper time. The ignition system consists of a battery, ignition switch, ignition coil, distributor, spark plugs, and wiring.

The very high voltage needed to jump the gap of the spark plugs is obtained from the ignition coil. This coil is a step-up transformer that steps up the voltage to over 20,000 volts. The battery supplies the voltage to the primary circuit of the ignition coil. However, since pure direct current cannot be used to induce a voltage in the secondary of a transformer, it is necessary to start and stop the battery current.

The starting and stopping or opening and closing of the primary circuit of the ignition coil is done by the distributor, which is usually driven by the engine camshaft. The distributor has a set of contact points that are opened and closed by a rotating cam which has the same number of lobes as the engine has cylinders. The camshaft, which is driven by the engine, rotates at one half the speed of the crankshaft. This opening and closing of the contact points by the cam starts and stops the current flow in the primary of the ignition coil so that voltage is induced into the secondary coil. A capacitor (condenser) is placed across the points to prevent the burning of the contact points and to reduce arcing.

The distributor delivers the high voltage produced by the secondary of the ignition coil to the correct spark plug at the proper time. This delivery is accomplished by the rotor in the distributor. The rotor attached to the distributor shaft is connected directly to the output of the ignition coil. As the rotor turns in the distributor, it moves from one contact point to the next in the distributor cap. Each of the contacts in the cap is connected by a high-tension cable to a different spark plug. Thus, as the rotor turns, it distributes the high-voltage surges first to one spark plug, then to another, and so on, according to the engine firing order.

High-compression engines require a higher voltage at high speeds for efficient ignition of the fuel. In the conventional system the points open and close quickly, and the primary coil does not have time to build up to a very high voltage. Other defects found in this system are the limited life of the points and capacitor, along with the maintenance necessary to keep these units in working condition.

The transistorized ignition system eliminates these defects and provides far more dependable service than could be obtained from the conventional system. The transistor, which is capable of handling large amounts of current, switches the primary circuit on and off so that the points carry only a very small current. Since the points carry

The ignition coil in a typical ignition circuit is shown schematically, with the magnetic lines of force indicated (Delco-Remy Division, General Motors Corp.).

14648

such a small portion of the total current, arcing between them is eliminated and a capacitor is not required. However, a special coil with a higher turns ratio and current rating must be used.

Some transistorized ignition systems do not use a contact point in the primary circuit. Instead, a magnetic pickup coil is used to time the transistor current flow for the primary circuit. A permanent magnet ring is mounted on the top of the distributor shaft. This magnet has the same number of teeth as there are cylinders in the engine. Inside of the permanent magnet is a pickup coil that is wound around a steel core, which also has teeth. Each time the teeth align, the magnetic lines of force from the permanent magnet cut through the turns of wire in the pickup coil. This activity produces the same effect in the primary circuit as does the opening of the contact points. The specialized transistorized circuit connected to the pickup coil acts as a current amplifier and switch to turn the primary coil circuit off and on.

Scientific Principle Involved: Electromagnetic Energy

When the primary circuit of the ignition coil is interrupted by the opening of the points in the distributor, the magnetic field produced in the core of the ignition coil collapses rapidly. The change in flux induces a high electromotive force in the secondary winding, whose voltage ratio, compared to the voltage of the primary, is the same as the ratio of the number of turns in the secondary winding to the number of turns in the primary.

The capacitor (condenser) consists of two conducting plates separated by an electrical insulator, usually two strips of metal foil separated by wax paper wound into a roll. It operates on the principle that an electrical charge placed on one plate of the conductor induces an opposite charge in the other plate, which is connected to ground. These opposite charges on the plates attract each other so that additional charges can be added to the charging plate. When the primary current to the induction coil is interrupted, the collapsing magnetic field induces a current in the primary winding as well as in the secondary. Rather than arc across the points, the primary current charges the capacitor. The capacitor then discharges back through the primary coil when the points are again on the make.

The high voltage on the center electrode of the spark plug produces a high rate of ionization of the gases in the fuel-air mixture in the combusion chamber. Sufficient force is supplied to the charged particles (ions) by the electric field to produce enough energy in the spark discharge across the gap to ignite the mixture, producing heat energy in the expanding gases as a result of the chemical reaction in the burning fuel.

The magnetic pickup coil used in some transistorized ignition circuits operates on the principle of electromagnetic induction, which produces an electromotive force whenever the flux through the coil changes. However, since this current is relatively small, timed voltage pulses are used to vary the bias on the transistor base to control the amplitude of the current through the primary circuit.

Ignition systems used on internal-combusion engines may be categorized as (1) the hot-tube or glow-plug types used on model airplane and diesel engines; (2) the magneto type; (3) the transistorized ignition; (4) the capacitor-discharge type; (5) the pulse pickup type; and (6) the conventional automotive-type ignition system. There are many other applications for ignition systems which employ the same basic principle; an example is the ignition system used for automatically fired gas furnaces, heaters, or steam cleaners.

Application of Principle

The students can do the following things:

1. Measure the voltage in the primary cirucit (approximately 6 to 12 volts in the automobile) and compare it to the measured secondary voltage (approximately 25 to 30 thousand volts, as measured with an oscilloscope).
2. Measure the voltage in as many ignition systems as are available and compare their primary and secondary voltages.
3. Measure the amperage flowing in the primary and secondary circuits of the conventional, transistorized, and magneto-ignition systems. Compare the amperage flowing in the primary of each system and discuss the implications of this comparison.
4. Demonstrate glow-plug ignition by connecting a model airplane glow plug to a 6-volt battery and observing the small coil of wire as it becomes red hot.
5. Examine and repair various ignition systems and their individual components.

Unit 28 — ELECTRIC MOTORS

An electric motor is a device that converts electrical energy into mechanical energy. Because of its ease of operation, efficiency, convenience, and economy of operation, it is used extensively in industry, in business, in the home, and in the automobile. Electric motors range in size from very small motors used to run electric clocks to very large motors used to operate industrial conveyor-belt systems.

Electric motors have a variety of characteristics, each of which is selected to meet the requirements that it must fulfill. The automobile has several different types of direct-current motors. One starts (cranks) the engine, another operates the blower of the heating/refrigeration system, and another raises and lowers the windows.

The motor used to start the engine in an automobile is a series-wound motor in which the field coils are connected in series with the armature coils. Series-wound motors have the advantage of developing a tremendous torque, which is essential when starting an automobile engine. Shunt-wound motors, which have the field coil connected in parallel with the armature coil, are used where constant speed is desired, such as for blowers. Another direct-current motor is called a compound-wound motor since it has one field coil in series with the armature and another in parallel with it. The compound-wound motor combines the starting torque of the series-wound motor with the constant speed of the shunt-wound motor. A rheostat is used to control the current flow in order to vary the speed of a direct-current motor.

The alternating-current motor is used extensively in the home and in industry, where alternating current is readily available. Alternating-current motors are usually classified as induction, universal, and synchronous motors.

The induction motor is the most common type used to operate industrial equipment such as drill presses, lathes, and grinders. Household equipment, such as washing machines, dryers, refrigerators, and disposals also uses induction motors. These motors are trouble-free and do not use the commutators or brushes found in direct-current motors. Induction motors require a starting system in order to get them rotating. There are a number of different systems used for this purpose. One of the most common methods of starting an induction motor is through the use of two sets of stationary windings. One winding is called the running winding and the other the starting winding. The starting winding is automatically disconnected from the circuit after the motor is in motion.

The universal motor is used where variable speeds are desired; it can be found in electric mixers and sewing machines. A rheostat is used to control the speed of a universal motor. The synchronous motor is used where constant speed is desired. The electric clock, which uses a synchronous motor, has a stator and a rotor with multiple poles.

Scientific Principle Involved: Electromagnetic Induction

An electric current flowing in a wire produces a magnetic field around the wire. If the wire is placed at right angles to a magnetic field, the interaction of the two magnetic fields produces a force on the wire, tending to move the force across the magnetic field. The amount of the force is directly proportional to the strength of current in the wire, the strength of the magnetic field in which it is placed, and the length of the wire. The direction of the force is determined by the direction of the movement of the electrons in the wire and the direction of the magnetic field in which the wire is placed. This interaction between magnetic fields is the underlying principle for the operation of all electric motors, where the attractions and repulsions between the magnetic fields of the armature (rotor) windings and the field (stator) produce the torque which turns the motor. The torque of the motor depends on the strength of the current, the number of windings in the armature, the number of turns in each winding, and the

14650

strength of current and number of turns in the field coils. All direct-current motors utilize a commutator and brushes to change the direction of current flow in the armature coils at just the right instant during the cycle in order to maintain the rotation. Direct-current motors may be reversed in the direction of rotation by reversing the current in either the armature or in the field windings, but not in both. The series-wound direct-current motor can be operated on alternating current because both the armature and the field windings change polarity simultaneously in step with the alternations in the current.

The diagrams show the wiring of (1) a direct-current series-wound motor; (2) a direct-current shunt-wound motor; and (3) a direct-current compound-wound motor.

The induction motor operates on alternating current only because the motor depends on the alternating magnetic field produced by the current in the stator to induce an alternating current in the rotor conductors. The current induced in the rotor is opposite in direction to the stator current; therefore, their fields are in direct opposition to each other. However, since a torque is necessary to produce rotation, the starting coil must have a current which is out of phase with the stator current. This change of phase of the stator coil is accomplished by either a capacitor or an induction coil, which causes the current to either lead or lag the impressed voltage. When the rotor approaches near-synchronous speed, the stator current is interrupted, and the alternations in the main stator coil which are out of phase with the induced current in the rotor will continue to supply torque to maintain the rotor at near-synchronous speed. The synchronous motor is a constant-speed motor because its speed of rotation is determined by the frequency (cycles per second) of the alternating-current power supplied to the stator and the number of poles on the rotor, in accordance with the formula $rpm = f \times 120 \div p$, where f = frequency of alternating current in cycles per second and p = number of poles.

Variable speeds are obtained in direct-current and universal alternating-current/direct-current motors by controlling the amount of current with a rheostat.

Since the electric motor is similar in construction to the electric generator, the rotating motor produces a current which opposes that being supplied to the motor. This opposition accounts for the fact that more current is required for starting an electric motor than for operating it at its designed speed.

Application of Principle

1. Laboratory activities involving all of the various types of electric motors would be virtually impossible. However, a list could be made identifying electrical motors by their type and utilization, such as AC, DC, induction, synchronous, series, shunt, and others;

14651

and the advantages and disadvantages of each could be discussed. Skills could be applied and the understanding of technical information extended through disassembly, testing, and study of the various circuits involved.

2. A simple demonstration which indicates the relationship between the amount of current required and the load applied to the motor is obtained by connecting to a battery an internal-combustion-engine starter motor which has been removed from the engine, and measuring the amperage required by the free-running starter motor. Next, the ammeter is connected to a starter motor which is installed on an engine, the engine is started, and the amperage required to turn the starting motor now that the load of the engine has been added is noted. The two amperage readings are compared and their implications are discussed.
3. Another common application involves varying the speed of electric motors. Sewing machines, as well as automobile-heater and air-conditioning blower-motors, utilize a motor which requires a varying speed. The circuits of such motors could be analyzed and discussed, such points being discussed as the necessity for variable speed and the precise means of accomplishing such speed. The various components, such as the brushes, commutators, and rheostats, which make possible the varying of the speed of an electric motor, can be physically examined.
4. Opposed to an electric motor, which must operate at an infinite number of revolutions per minute, the synchronous motor must maintain continuous revolutions per minute. The rpm of the synchronous motor is controlled by the frequency of the alternating current and the number of poles in the motor. An example of a synchronous motor which should be examined is an electric clock.

Unit 29 — FUEL CELLS

Scientists are working constantly to find new methods for generating electrical power. One method that has great promise is the fuel cell. This cell has been used to develop electrical power inside spacecraft that have carried astronauts into outer space.

Fuel cells produce a continuous flow of electricity by means of chemical action. These cells create electric energy with greater efficiency than do most other electrical generators. A fuel cell can produce electricity as long as it is fed fuel along with oxygen or air. Dry-cell batteries work on a similar principle but cannot be fed continuously with fuel.

The fuel cell consists of electrodes; an electrolyte; a fuel, such as hydrogen gas; and an oxidizing agent, such as oxygen. In the hydrogen-oxygen fuel cell, catalytic nickel is used for electrodes, and the electrolyte is potassium hydroxide. Oxygen is fed to the positive electrode and hydrogen to the negative electrode. The result of the chemical action in the cell is the production of water, which must be removed to maintain the proper electrolyte concentration. The voltage output is approximately 1 volt per fuel cell. Because of the high cost of producing a fuel cell, its use is limited at the present time.

In Gemini spacecraft the smallest active element of the fuel-cell battery is the thin individual fuel cell, which is 8 inches long and 7 inches wide. Each cell consists of an electrolyte-electrode assembly with associated components for gas distribution, current collection, heat removal, and water control. In the fuel-cell battery for the Gemini, 32 cells are series-connected to form a module. Terminal plates installed on the ends of the two outside cells in the module serve as electrical connectors for the external circuitry. Each module has its own hydrogen and coolant manifold as well as its own water-oxygen separator. Three modules containing a total of 96 single fuel cells are installed in a cylindrical container to form a compact fuel-cell

14652

battery. The three modules are electrically independent and are connected in parallel through connections to the main electrical bus. The fuel-cell batteries may also be connected in parallel with the reentry batteries. Fuel cells are highly efficient; they have an overall thermal efficiency of more than 50 percent. They are capable of producing more electricity per pound of fuel than all but nuclear devices. The fuel-cell batteries are silent, fumeless, and operable without moving parts.

Scientific Principle Involved: Electrochemical Effect

The fuel cell is an electrochemical cell in which the energy of the chemical reaction between oxygen and a gaseous fuel such as hydrogen, natural gas, or carbon monoxide is converted directly into low-voltage, direct-current electrical energy. In the hydrogen-oxygen cell, hydrogen gas passes through the porous nickel electrodes and reacts with the hydroxide ions of the electrolyte. This reaction forms water and gives up electrons to the electrode. When an external circuit is completed to the oxygen-fed electrode, these electrons move to this electrode and enter into the chemical reaction, where the oxygen reacts with water to form negatively charged hydroxide ions. These ions replace those which were used up at the hydrogen-fed electrode. The net result of these reactions is the combination of hydrogen and oxygen to form water in the cell and the movement of electrons from the hydrogen-fed cathode to the oxygen-fed anode. In addition to acting as an electrical conductor, the porous nickel in the electrodes serves as a catalyst by breaking down molecules of the hydrogen and oxygen gases into separate atoms, helping to speed up the chemical reactions at the electrodes. Since the electrodes do not enter into the chemical reaction in this cell, they do not deteriorate as in the conventional electrochemical cell.

In Gemini spacecraft, ion-exchange membrane fuel cells convert the energy of the chemical reaction of hydrogen and oxygen directly into electricity. Unlike conventional batteries, fuel-cell batteries will continue to operate as long as hydrogen and oxygen are fed from an external source. The structure of the fuel cell contains an anode and cathode, which are in contact with a solid plastic electrolyte (ion-exchange membrane) that permits the exchange of hydrogen ions between electrodes. In the presence of a metallic catalyst, hydrogen gives up electrons to the load (where they do useful work as an electric current) while releasing hydrogen ions, which migrate across the electrolyte to the cathode. There the ions combine with oxygen and electrons from the load circuit to produce water, which is carried off by wicks to a collection point. Ribbed metal current-carriers are in contact with both sides of the electrodes to conduct the produced electricity. The fuel batteries and the fuel and oxidant supply are located in the spacecraft-equipment section. Total consumption is approximately 0.9 pound per kilowatt hour. Fuel and reactant flow is regulated to delivery pressure by a dual pressure regulator and relief valve. By-product water from the fuel-

The hydrogen-oxygen fuel cell uses catalytic nickel electrodes and an electrolyte of potassium hydroxide.

cell battery provides a pressure reference for the reactant gases.

Application of Principle

Fuel cells are classified as one of the more exotic power sources in use today. Most of the fuel cells produced are used for scientific experimentation and military or specialized industrial applications. One source of information concerning laboratory activities relating to various types of fuel cells is contained in the laboratory manual (pp. 135-40) for the following book, which was written by Joseph W. Duffy: *Power: Prime Mover of Technology* (First edition). Bloomington, Ill.: McKnight & McKnight Publishing Co., 1964.

Unit 30 — PHOTOELECTRIC CELLS

Some modern automobiles have automatic headlight dimmers and automatic light switches. These devices are operated by a photoelectric cell, which is used to convert radiant energy into a flow of electric current.

The first photoelectric cells used the photoelectric vacuum tube as the control device. The photoelectric tube can provide electric current for operating devices that will turn on burglar alarms, open doors, pick up sound in the sound motion-picture projectors, and control a variety of devices. Certain materials (such as potassium, sodium, selenium, and cesium) will give off small quantities of electrons when held in ordinary light. When light is focused on the material in the vacuum tube, a positive anode will attract the electrons which are emitted. The current flow in the phototube, which is very small, is usually increased by an amplifier. The output of the amplifier can be connected to a relay that will turn a circuit on or off.

Most present-day photoelectric cells use solid-state materials in which a small voltage can be produced when light shines on the material. These solar cells, called photovoltaic cells, use two types of material which generate a voltage at a junction between the material when light shines on the surface. A good example of such a device is the light meter used in photographic meters where the output of the cell is connected to a sensitive galvanometer. The stronger the light, the greater is the voltage produced by the cell. The increase or decrease of the cell voltage is determined by reading the needle movement in the galvanometer.

The automatic headlight switch used in the automobile turns the car lights on or off according to the light level. As evening approaches and daylight is reduced to the point where lights are needed, the photoelectric cell turns the car lights on. The photoelectric cell, which is mounted behind the windshield, is exposed to the light. This cell is connected to a transistor amplifier circuit which operates a sensitive relay. This relay is connected to a power relay that turns on the car lighting system.

Scientific Principle Involved: Photoelectric Effect

Photoelectric devices depend on the absorption of incident light (infrared through ultraviolet) by electrons in the sensitive material to alter the electric characteristics of the material. According to the quantum theory of light, photons are the small bundles of energy or quanta associated with light radiation. Since the energy of the photon depends on the frequency of the light wave, photons of ultraviolet light (higher frequency) have more energy than visible and infrared light. When an electron in a material absorbs a photon of radiant energy, it may be released from its bonds within the material, and its energy of motion will depend on how much energy it absorbs from the

Light falling on certain metals, such as selenium or cesium, produces an electric current.

14654

photon and how much of that energy was used in breaking the bonds. The magnitude of the photoelectric effect is determined by the intensity (number of photons) of radiation absorbed.

In the vacuum or gas-filled phototube, the sensitive element (cathode) is coated with a metal, such as potassium or cesium, which emits electrons from the surface when subjected to incident light. These photoelectrons are accelerated toward a positive anode in the same way as in the conventional electron tube.

Photocells which use a single semiconducting material, such as selenium or cadmium sulfide, depend on the photoelectric effect to produce pairs of free electrons and positive holes within the material. This increase in the number of free electrons and positive holes results in the proportional increase of conductance of the cell in the battery-powered circuit.

Photovoltaic cells, such as the solar cell, use two different semiconducting materials in contact with each other to form an N-P barrier. In the N-type material, such as selenium- silicon, conduction is due to excess free electrons; in the P-type material, such as boron-silicon, conduction is due to the excess positive holes. This separation of electrical charges produces an electrical field across the barrier. When light is absorbed at the barrier region, new pairs of free electrons and positive holes are produced by the photoelectric effect. The increase in the number of free electrons in the P-type material allows the more energetic electrons to move across the barrier into the N-type material, where they are free to move and deliver electrical power in the external circuit.

Application of Principle

1. Demonstrate the characteristics of photovoltaic cells by connecting a cell (silicon, selenium, or the like) to a milliammeter. Expose the cell to ordinary light and observe the action of the milliammeter (0-1). Vary the intensity of the light and note the meter readings also vary in direct proportion to the intensity of light striking the photovoltaic cell.
2. Use an ordinary lightmeter to measure the available light when taking photographs. Record the readings as the meter is exposed to direct and indirect light in varying degrees. Also note the change in the meter reading as the color of the subject or background changes.

Unit 31 — SEMICONDUCTOR POWER RECTIFIERS

In certain electronic circuits it is desirable to convert alternating current into direct current. Such devices as radio receivers, television sets, stereos, and tape recorders all require a source of direct current. To obtain the necessary direct current from an alternating-current power source, each of these pieces of equipment uses a rectifier. The rectifier changes the alternating current into direct current.

In the modern automobile the alternating-current generator, called an alternator, also must have the alternating-current output rectified to direct current so that the storage battery can be kept charged. With the increased electrical demands in the automobile, the alternator is replacing the direct-current generator because of its efficiency and generating capabilities at low speeds.

Vacuum tubes can be used as rectifiers, but in many devices they are being replaced by solid-state semiconductors. These semiconductors, called diodes, will permit current to flow through the conducting material quite easily in one direction. When the current is reversed, the semiconductor offers a great deal of resistance to the flow of current. Thus, the semiconductor diode will permit current to flow in one direction only; and when connected in an alternating-current circuit, the output from the diode is direct current.

The early semiconductor power rectifiers – copper oxide, copper sulfide, and selenium – were known as dry rectifiers. At the present time germanium or silicon are being used for solid-state rectifiers, which are usually mounted in the slip-ring end of the alternator.

14655

When a single diode is used as a rectifier in an alternating-current circuit, the output, after passing through the diode, will be pulses of direct current. Direct current will flow only during half of the alternating-current cycle since the diode will permit current flow in one direction only. So that a much smoother direct current can be obtained, it is possible to design a circuit called a full-wave rectifier that will rectify both halves of the alternating cycle. The output provides a much smoother flow of current since two pulses of direct current are produced for each cycle of alternating current. Such a circuit, called a bridge-rectifier system, uses four diodes.

In the automobile it is very desirable to have a fairly smooth direct current for charging purposes. Three stator windings are, therefore, used in the alternator and are connected in either a "Y" connection or a "delta" connection. This arrangement enables the generator to produce a three-phase alternating current which provides overlapping cycles of alternating current. The output of the three-phase current is connected to six solid-state diodes so that the output from the rectifiers is a fairly constant direct current. Since diodes produce heat when they are conducting current, it is necessary to use special devices called heat sinks to absorb this energy. The diodes are placed inside the alternator, and the heat sinks have large radiating surfaces to allow the heat to be radiated into the air surrounding the generator.

Scientific Principle Involved: Rectification with Semiconductors

Silicon and germanium are quite similar in their structure and chemical behavior. The atoms of both elements have four electrons bound in the same way in their respective crystals. In its transistor functions germanium is the more versatile semiconductor. Germanium acquires the diode property of rectification and the transistor property of amplification through the presence of certain impurities in the crystal structure. Two types of impurities are important; one is known as a donor, the other as an acceptor.

Arsenic and antimony are typical donor elements. When minute traces of antimony are added to germanium, each antimony atom donates one electron to the crystal structure. Four of the five electrons are paired, but the fifth electron is relatively free to wander like the free electrons of a metallic conductor. The detached electron leaves behind an antimony atom with a unit positive charge. Germanium with this type of crystal structure is called N-type, or electron-rich germanium. N-type germanium consists of germanium to which are added equal numbers of free electrons and bound positive charges so that the net charge is zero.

Atoms with three electrons, such as those of aluminum and gallium, will act as acceptors. When minute traces of aluminum are added to germanium, each aluminum atom accepts a single electron from a neighboring germanium atom, leaving a hole in the electron-pair bond from which the electron is acquired. This hole is the equivalent of a positive charge since it acts as a trap into which an electron can fall. As an electron fills the hole, it leaves another hole behind into which another electron can fall. In effect, then, the hole (positive charge) detaches itself and becomes free to move, leaving behind the aluminum atom with a unit negative charge. Germanium with this crystal structure is called P-type, or hole-rich germanium. P-type germanium consists of germanium to which is added an equal number of free positive holes and bound negative charges so that the net charge is zero.

Both P-type and N-type crystals are good conductors, and each will conduct equally well in either direction. When the two types are joined together, however, an electric barrier is established where their surfaces meet. The plane at which the P-type crystal meets the N-type crystal is called the P-N junction. The free holes of the P crystal cannot pass through the electric barrier at the P-N junction to reach the N crystal; the free electrons of the N crystal cannot cross the P-N junction to reach the P crystal.

A small potential difference impressed across the pair enables the free electrons to cross the junction

A small potential difference impressed across the P-type and N-type crystals enables the free electrons to cross the junction and pass into the P-crystal.

14656

and pass into the P crystal. Similarly, the holes cross into the N crystal. The apparent movement of holes is in the opposite sense to the actual movement of electrons which fall in the holes of the P-type crystal. Thus, an electron movement is established across the P-N junction and in the external cirucit.

If the battery connections are reversed, the free electrons in the N crystal and the free holes of the P crystal are attracted away from the P-N junction. The junction region is left without current carriers; consequently, there is no conduction across the junction and no current in the circuit.

It is the junction which has the distinctive property of permitting electron movement in one direction with ease when a small voltage is applied in the proper sense. Thus, the P-N junction is the rectifying element of semiconductor crystals.

Application of Principle

A characteristic of solid-state rectifiers, such as the diodes used in automobile alternators, is that they will allow current to flow in one direction only. This characteristic may be demonstrated, and at the same time the diode may be checked for opens and shorts, by using an ohmmeter.

1. Select a diode, either positive or negative case, from an alternator. If a negative-case diode is selected, connect the negative lead of the ohmmeter to the case of the diode. Next, connect the positive lead of the ohmmeter to the positive lead of the diode. Reverse the connections when checking a positive-case diode. Although there may be a wide variation in the resistance of different diodes, the ohmmeter reading should be consistently above 300 ohms. If the reading is below 300 ohms, the diode has probably been shorted and should be replaced.
2. Check an open circuit in a negative-case diode by connecting the negative lead of the ohmmeter to the positive lead of the diode and the positive lead to the negative case of the diode. Reverse the connections when checking a positive-case diode. If an infinite resistance is indicated by the ohmmeter, the diode has an open circuit and should be replaced. *Note:* If the diode is good, there will be no current flow when the ohmmeter is connected as indicated previously. However, reversing the connections on the diode will cause a current to pass through the diode.

SECTION VI
HYDRAULIC POWER

Unit 32 — JACKS AND PRESSES

Through the use of hydraulics, the strength (muscle power) of a person can be multiplied thousands of times. For example, it is possible through the use of hydraulic jacks for a person to lift a part or all of a house. Hydraulic tools are used extensively in the automotive industry. Whenever a heavy force must be applied or a heavy weight lifted, a hydraulic tool has been designed to provide the means.

A hydraulic jack or press consists of large and small cylinders connected at their base by a small tube or internal passage. A piston fits into each cylinder. When a force is applied to the handle at the small piston, a pressure is developed in the small cylinder. The pressure developed depends on the area of the small piston and the force applied. This pressure is carried through the hydraulic line to the large cylinder. In this cylinder the pressure is applied to the large piston, forcing it to move.

In the simplified diagram of a hydraulic press, a lever is attached to the small piston. As the small piston is pushed down, some of the liquid from the small cylinder (1) is forced into the large cylinder (2). This pressure raises the large piston a small amount. As the lever is worked up and down, it pumps the liquid from the reservoir and forces it into the cylinder (2). When the pressure is to be

released, the reservoir valve is opened to let the liquid flow from the cylinder (2) back into the reservoir.

The force is determined by the pressure and the area of the pistons. For example, the small piston has an area of 1 square inch and is connected directly to the larger piston, which has an area of 100 square inches. If a force of 200 pounds is applied to the small piston, a pressure of 200 pounds per square inch is developed. This pressure is transmitted to the larger cylinder, which has a piston area of 100 square inches. This piston is, therefore, pushed with a force of 20,000 pounds (100 sq. in. X 200 lbs. per sq. in.) This gain in

14658

force (from 200 to 20,000 pounds) is made at the expense of distance moved. If the small piston moved 5 inches, the large piston moved 5/100 of an inch. The output force could be doubled by decreasing the size of the small piston and cylinder to ½ square inch. However, the distance moved would be halved.

The force of 200 pounds applied to the small cylinder is easy to obtain. Most jacks, presses, and cranes have handles which are used to apply the force to the small cylinder. These handles are arranged as levers and multiply the applied force at the expense of distance. The 10-ton (20,000-pound) jack used as an example is relatively small, but 60- and 80- ton jacks are available. The output force is very high; however, movement is quite slow because of the tremendous mechanical advantage needed to multiply a 50- to 100-pound force to an 80-ton force.

Scientific Principle Involved: Pascal's Principle

A hydraulic pump or set of cylinders does not "pump" pressure. It merely produces a flow of hydraulic fluid. Pressure is generated only when a restriction or load is placed in the circuit. If the flow encounters negligible resistance, the developed pressure is negligible. As the resistance force increases, the pressure within the system produced by the pump (or cylinders) increases to meet the resistance force. The mechanical advantage produced by a set of hydraulic cylinders is equal to the ratio of the surface area of the pistons. This ratio determines the ratio of distances moved by each cylinder, another measure of the mechanical advantage.

Pressure applied anywhere on a confined liquid or gas is transmitted undiminished in every direction. The force thus exerted by the confined liquid or gas acts at right angles to every portion of the surface of the container and is equal upon equal areas (Pascal's principle).

Application of Principle

1. The mechanical advantage of hydraulic jacks can be determined by measuring and comparing the distance the small and large pistons move.
2. Different weights can be placed on the jack to show that a resistance is necessary to produce a mechanical advantage. A comparison of force applied to the weight lifted can also be calculated by operating the jack handle through a spring scale. The efficiency of the jack can be shown by a comparison of the theoretical mechanical advantage and the actual mechanical advantage.
3. Hydraulic devices can be disassembled and assembled to assist in understanding the operation of each part. The exact theoretical advantage of the hydraulic parts can be provided by the measurement of piston sizes.

Unit 33 — MACHINE TOOLS

Many machine tools use hydraulic systems to control the movement of machining operations. Hydraulic systems provide rapid, accurate, and efficient control of intricate machine functions. Hydraulic power, as applied to tools and machines, relies on the principle that liquids can't be compressed. Liquids under pressure transmit the pressure throughout all parts of the fluid. This basic property allows the use of a liquid to transmit power from its source to the desired point of application by means of transmission lines (pipes or tubes).

In many applications hydraulic systems are more efficient than mechanical linkage or a train of gears. In addition, hydraulic systems are more flexible in terms of load, speed, and mechanical advantage. The basic system consists of an electric motor driving a hydraulic pump and other rotating parts of the machine. The hydraulic pump operates a hydraulic system consisting of control valves, cylinders, and gauges or sensing devices. Both vertical and horizontal motion of tables and machine platforms can be operated and controlled by the hydraulic system.

14659

Simple valving permits accurate control of a hydraulically actuated shaper.

Scientific Principle Involved: Pressure Transmission by Liquid

Liquids, when subjected to pressure changes, transmit the pressure change to all parts of the fluid undiminished (Pascal's principle). This principle may also be stated as follows: Pressure applied anywhere on a confined fluid is transmitted undiminished in every direction. The force thus exerted by the confined fluid acts at right angles to every portion of the surface of the container and is equal upon equal areas. Note that fluids may be either liquids or gases; Pascal's principle applies to both of these states of matter.

Application of Principle

Devices in which liquids are used to transmit pressure, such as hydraulic presses, lifts, and brakes, can be examined, tested, and operated. Pressure gauges can be placed in the system to determine the system's pressure. Cylinders can be measured and the pressure converted to force to determine the force being used to produce a particular motion. Machines can be adjusted as follows to demonstrate the hydraulic principles:

1. The speed of the machine can be changed by restricting liquid flow.
2. An increase in pressure can be demonstrated by increasing the work load.

(6), pp. 3-6; *(27)*, pp. 200-202; *(36)*, pp. 54-58; *(69)*, Chapter 18, p.2; *(80)*, pp. 463-72.

Unit 34 — BRAKING SYSTEMS

Devices for retarding or stopping motion are found in many pieces of equipment. The basic type of braking operation is a band tightened around or a pad pressed against a wheel in motion. Braking can be assisted by regulating the movement of fluids (liquids or gases), controlling the flow of electric current, reversing the rotation of ship propellers, reversing the pitch of airplane propellers, closing the clam-shell doors of jet engines, or pressing a disk against the face of a wheel.

In the braking systems of vehicles that move on wheels (such as automobiles, motorcycles, and

14660

scooters), the friction between brake drums and brake shoes or between pads and metal disks slows the rotation of the wheels; however, it is the friction between the tires and the road that results in the stopping of the vehicles.

The application of hydraulic force is almost universal in the braking systems of modern automobiles. The modern hydraulic system is a combination of mechanical linkage and force transmitted through liquids to the brake shoes or disks. Power brakes use a pneumatic cylinder operated by the engine vacuum to increase the ease and efficiency of the braking force. The efficiency of the braking force continues to grow in importance as automobile speed increases and automobile safety receives greater attention.

In sectional view (1) the disk brake is in a released position; in (2), the brake is in an applied position because of the hydraulic pressure (3) from the master cylinder.

A practical application of force distribution through liquid pressure is found in the four-wheel hydraulic brake system of the automobile. When force is applied to the foot pedal, a pressure is transmitted equally throughout the system to each wheel by the employment of the mechanical advantage of levers. At the road wheel hydraulic cylinders convert force through mechanical linkage to the brake shoes or friction pads. Release of pressure on the foot pedal reduces liquid pressure in the system, and spring tension returns to the original position all components, such as pistons, springs, and shoes.

Scientific Principle Involved: Pascal's Principle

Total force is the force acting against the entire area of a particular surface. A liquid exerts a total force against the entire area of the bottom and sides of its container. Since liquid pressure equals force per unit area, total force equals the product of the average pressure on the area times the entire area.

The principle of the transmission of force by a liquid can be illustrated as follows: If a force of 50 pounds were applied to a piston at a master cylinder whose area was 2 square inches, the 50 pounds of pressure would be distributed equally so that each square inch would produce 25 pounds of force. The force applied at each wheel cylinder would be 25 pounds if the cylinder had an area of one square inch. Force can be increased by enlarging the diameter of the output cylinder or by increasing the pressure per square inch (psi).

A schematic of a typical hydraulic system shows how brake shoes are activated to press the brake lining against the brake drums.

14661

Application of Principle

Instruction relating to basic hydraulic principles can be furthered through activities involving the service and repair of automotive hydraulic brake systems. Some of the activities students can perform are as follows:

1. Measure the pressure developed in a brake system.
2. Calculate the force developed at each brake shoe.
3. Service and repair automotive brakes.
4. Determine the compressibility of air as compared to brake fluid by allowing air to be admitted into the system.

Unit 35 — FUEL PUMPS

The fuel pump is a simple example of the hydraulic pump used in almost all hydraulic applications. Power steering in the automobile is another application of the hydraulic pump. Many machines, jacks, and automobile lifts use hydraulics as their principal form of power. Production processes in industrial plants make extensive use of hydraulics.

The hydraulic fuel pump is designed to supply gasoline to the carburetor of an internal-combustion engine at a constant low pressure. It is a positive displacement pump using a diaphragm driven by a spring to develop and maintain pressure on the outlet side. In operation the diaphragm of the fuel pump is pulled back on the intake stroke by the action of the engine camshaft. As the diaphragm moves back on the intake stroke, a partial vacuum is produced in the fuel chamber. Atmospheric pressure acting on the fuel in the tank pushes it through the fuel lines, past the inlet valve, and into the fuel pump chamber. When the diaphragm is released, a spring located behind the diaphragm pushes the diaphragm forward, placing a pressure of approximately 6 pounds per square inch on the fuel in the chamber. This pressure forces the fuel against the inlet valve, closing it. When the carburetor needle valve opens, relieving the pressure in the line between the fuel pump and carburetor, the diaphragm moves forward, pushing fuel through the outlet valve and into the carburetor. The spring and diaphragm maintain an almost constant pressure on the fuel, thereby providing a continuous supply of fuel to the carburetor.

An electric fuel pump is used on some heavy-duty equipment, such as trucks and buses. This fuel pump contains a flexible metal bellows that is operated by an electromagnet.

Certain internal-combustion engines make use of the fuel-injection system. Instead of a carburetor this system uses a series of injection nozzles and a high-pressure fuel pump to spray the fuel into the air entering the engine cylinders.

Scientific Principle Involved: Atmospheric Pressure

Liquids will always flow to balance a pressure differential. When the pressure within the fuel pump chamber is reduced below atmospheric pressure (14.7 pounds per square inch) by the action of the diaphragm, atmospheric pressure within the gasoline tank pushes the gasoline from the tank into the fuel pump chamber, balancing the pressure within the tank and fuel pump chamber at atmospheric pressure.

The illustration presented above shows a typical fuel pump in which the movement of the diaphragm produces a partial vacuum.

C0014662

Application of Principle

1. Disassemble and assemble a fuel pump, studying the operation of each component part. Determine the operating characteristics of the total pump and the contribution of each part to the operation of the pump.
2. Test the fuel pumps in three ways – for volume, vacuum, and pressure – as follows:
   a. Conduct the volume test by disconnecting the outlet line of the fuel pump and pumping gasoline into a measured container. Run the engine at idle speed on the fuel remaining in the carburetor. In a specified time compare the output with the manufacturer's specifications.
   b. Conduct the vacuum test by attaching a vacuum gauge to the inlet side of the fuel pump. Operate the fuel pump and compare the obtained vacuum with the manufacturer's specifications.
   c. Conduct the pressure test by attaching a pressure gauge to the outlet side of the fuel pump. Operate the fuel pump and compare the obtained pressure with the manufacturer's specifications.

Unit 36 — POWER STEERING

Steering an automobile by moving the steering wheel manually has become more difficult because of increased weights and the use of wide, low-pressure tires. Ratios between the steering wheel and road wheels have been increased to compensate for the greater force needed to turn the automobile. A method of obtaining additional force to turn the wheels is the power-steering assembly. Power steering is a hydraulic system designed to assist the driver in turning the wheels of the automobile. During the past years a number of systems have evolved. Each, however, consists of a hydraulic pump driven by the automobile engine. The hydraulic fluid, under pump pressure, is controlled by a series of valves which direct the fluid to the proper chambers to assist the driver in turning the automobile.

The hydraulic pump is the heart of any hydraulic system. The pump develops no power of its own; it simply converts work applied to its drive shafts into the movement of a volume of oil under pressure. The volume is expressed in gallons per minute (gpm) and the pressure in pounds per square inch (psi). The two types of hydraulic pumps in common use are the positive-displacement pump and the nonpositive-displacement pump. The nonpositive-displacement pump uses the centrifugal force caused by rotation to move large quantities of fluid at low pressures. The automotive-engine water pump is of this design. When permitted to operate freely, it moves large quantities of water through the cooling system. If the system is restricted, as it is when the engine is cold and the thermostat is closed, the pump will simply rotate without movement or displacement of water.

The vane-type power-steering pump provides additional force to assist in turning the wheels of an automobile (Ford Motor Co.).

All power-steering systems use a positive-displacement pump. For each revolution of the pump shaft, a specific quantity of fluid is displaced; i.e., pumped into the outlet line. Positive-displacement pumps have the advantage of (1) capability for pumping high pressures;

14663

PATTERN ADJUSTMENT FOR SQUARE SHOULDERS

Diagram shows bodice back and front pattern pieces with needed adjustment lines indicated.

SBAL 48
1463

(2) minimum size; (3) relatively high volumetric efficiency; (4) relatively small change in efficiency throughout the pressure range; and (5) great flexibility of performance. Most power-steering pumps on today's vehicles are based on a vane design or a modification of this design.

Some power-steering systems use a simple hydraulic cylinder connected to the steering linkage to assist the turning. In these systems fluid under pressure is pumped to one side of the cylinder. The pressure of the fluid in the cylinder forces the piston to move within the chamber. Since the piston is connected to the steering linkage, the movement of thepiston helps turn the automobile wheels. In some cases the piston is stationary and the cylinder is connected to the linkage. In this case the movement of the cylinder assists turning.

Scientific Principle Involved: Pressure Transmission by Liquids

Hydraulic fluids under pressure exert a force in every direction within a closed container. The force resulting from the pressure is determined by the pressure and the surface area on which the pressure is applied. When the pressure is applied to a movable piston (or stationary piston and movable cylinder), the resultant force is equal to the pressure per square inch (psi) times the area of the piston, measured in the same units (square inches).

Application of Principle

1. Power-steering systems can be tested on the automobile for operating pressure, flow (gpm), and relief-valve setting – maximum system pressure. By the installation of an engine tachometer, a decrease in engine speed will be noted when the pump is operating at maximum pressure.
2. Through the use of selected power steering components or purchased hydraulic pumps, motors, and cylinders, a number of devices can be constructed as follows:
   a. A drill-press vise can be made to operate hydraulically by the use of a hydraulic cylinder and pump.
   b. A hydraulically operated can crusher can be built through the use of a hydraulic cylinder and pump in addition to a chamber to hold the can being crushed.
   c. A pencil sharpener can be operated hydraulically through the use of a hydraulic pump and a motor.

Unit 37 — AIR CONDITIONERS

Automobile air conditioners are designed to make the interior climate of the automobile comfortable during summer driving. This comfort is attained by removing both heat and water vapor from the air automatically. As the temperature of the air is lowered, the ability of the air to hold water decreases. The air reaches its coldest temperature in the car and air conditioner when it passes over the cooling coils (evaporator). Water vapor in the air condenses and is deposited on the cooling coils. The water is collected at the bottom of the coils, and a hose carries the condensed water to the ground under the automobile.

The automobile air conditioner uses the same principle of operation as that used by most home refrigeration units and industrial air conditioners. These systems use the principle that when a liquid changes to a gas, heat energy is required. The heat for this change of state comes from the surrounding materials and air. The change takes place at a constant temperature. The temperature at which this change of state takes place is, however, dependent upon the pressure placed above the liquid. As the pressure increases, the temperature at which the change of state occurs increases.

Freon-12, an odorless and nontoxic chemical consisting of carbon, fluorine, and chlorine, is the most common liquid used as a refrigerant in automobile air conditioners. At atmospheric pressure Freon-12 (F-12), boils at 21.7 degrees F.

014664

below zero. At a pressure of 42 pounds per square inch, F-12 boils at 45 degrees F., which is a more practical temperature for air conditioning. Each pound of F-12 which changes to a liquid removes 70 British thermal units of heat. The heat comes from the surrounding air. Since heat is a form of energy, the removal of this energy from the air lowers the temperature of the air.

In this process the refrigerant is changed from a liquid to a gas. The gas is carried to a compressor, where the pressure is raised to 150 to 160 pounds per square inch. The boiling temperature is, therefore, increased to 115 to 120 degrees F. This temperature is above the normal air temperature. The high-pressure, high-temperature gas is pumped to a condenser next to the automobile radiator. At normal summer temperatures of 85 to 100 degrees F., air passes over the radiator, removing heat from the condenser and gas. As heat is removed, the refrigerant changes back into a liquid. If the outside temperature is higher than noted, the condensing pressure will increase to maintain a temperature of 20 to 30 degrees F. above the outside temperature.

When the gas is condensed into a liquid, the liquid flows back to the evaporator inside the automobile. Through the use of a valve or restrictor, the pressure is reduced to around 45 pounds per square inch. The refrigerant can again evaporate and remove more heat from the interior of the automobile. The air-conditioning cycle is continuous; the refrigerant is changing state in both the evaporator and condenser at all times during operation. Since the refrigerant is just "a carrier of heat energy," it is never expended. It need be replaced only if the system develops a leak.

The heat pump, sometimes used for home heating, is a reversal of the air-conditioning cycle. The evaporator is outside and takes heat from the outside air and discharges it through a condenser

The state of the refrigerant at certain points in the air-conditioner unit is indicated in the diagram.

1024665

into the home. In the summer the system can be reversed through the use of valves to cool the home.

Scientific Principle Involved: Heat Transfer

During the change of state of a liquid, heat energy is either absorbed or expended at a constant temperature. This form of heat transfer is called "latent heat of vaporization." The amount of heat being removed or added depends upon the substance. Water has a higher latent heat of vaporization than any other common substance. It takes 970.4 British thermal units of heat to change one pound of water to one pound of steam. Water would make an excellent refrigerant except that in order to get water to boil at air-conditioning temperatures of 40 to 60 degrees F., the water must be under a vacuum of more than 20 inches of mercury. This pressure is inefficient since a very large compressor would be required to operate the system.

Application of Principle

1. An automobile air conditioner can be used for student demonstration and activities. Also, a teaching system can be developed by obtaining a refrigeration or air-conditioning system and providing it for student use.
2. Gauges can be put on both the high and low sides of the unit to determine the operating pressures and temperatures at which the change of state is taking place in the evaporator and condenser.
3. Possible leaks can be checked through the use of a leak detector or a solution of soap and water on all joints.
4. A compressor can be disassembled and assembled and the operation of the compressor studied.

14666

SECTION VII
PNEUMATIC POWER

Unit 38 — AIR-POWERED TOOLS

Air-powered (pneumatically operated) tools are particularly useful because they are relatively light and small, run cool, and have variable speed and torque. A few of the operations that can be performed by air-powered tools are drilling, sanding, grinding, chipping, tightening, and hammering. Other devices commonly found in industrial arts that depend on compressed air for their operation are spray guns, automatic feeds on printing presses, lubrication equipment, lifts, and jacks. In order that this flexible source of power can be used, an adequate supply of compressed air is needed, and hose connections should be conveniently located in the facility.

Air motors in air-powered tools require a pressure of approximately 90 pounds per square inch for efficient operation. A satisfactory source for obtaining this air pressure is the compressor in the automotive or woodworking facility; the compressor usually provides a pressure of 150 pounds per square inch. An air-powered tool is comprised of an air motor, housing, valve with lever, gears, spindle, and attachment to do the work. Motion in air-powered tools is produced in several ways. One method makes use of high-velocity air directed at a paddle or turbine wheel. The forced air causes the wheel to rotate like a waterwheel. Another method makes use of the relationship between pressure and volume. This second method is used to operate piston and rotary-vane motors, the two most common types of motors used in air-powered tools. These tools use reciprocating parts to accomplish work. Examples of these tools are the sheet-metal nibbler and the impact wrench used to tighten or loosen lug nuts on automobile wheels.

Scientific Principle Involved: Mechanical Properties of Gases

Two types of motors used to power air tools are the rotary type and the percussion or reciprocating type. In the first type a rotor with vanes is surrounded by a housing, usually made of cast aluminum. Air enters the housing, pushes on the vanes, and rotates a central shaft. The drill chuck or grinding wheel is fastened to the end of the central shaft. In the second type compressed air enters a cylinder and moves a piston that is connected to or strikes another part such as a chisel or riveting hammer. The pressure of compressed air and gases is frequently measured in atmospheres. One atmosphere of pressure is equal to 14.7 pounds per square inch (standard atmospheric pressure). When air is under a pressure of several atmospheres, it can exert a great expansive

14667

Photographs and exploded views illustrate units and components of air-powered tools (screwdrivers, nutsetters, and drills): (1) lever handle and (2) pistol handle (Stanley Air Tools).

14668

force, and this force can be transmitted for a great distance through strong-walled tubes.

A bicycle pump is the simplest positive-displacement compressor. The piston, secured to a handle by a long rod, has a cup-shaped leather face opening downward when the pump is in use. The downward motion of the piston causes sufficient initial pressure to open up the cup and produce a tight seal between the leather and the cylinder wall. Air is forced through the ball-check valve into the tire.

The upstroke of the piston creates a partial vacuum inside the cylinder, permitting atmospheric air to flow past the cup leather and filling the cylinder with air so that the cycle may be repeated. The flexible cup leather actually serves the function of a check valve because it opens to admit air into the cylinder (on the upstroke) but prevents the escape of air from the cylinder (on the downstroke) as air pressure forces the edges of the leather tight against the inside of the cylinder.

Reciprocating air or gas compressors operate on the same principle as the bicycle pump but with design changes made in the interest of ruggedness, efficiency, and durability.

Application of Principle

1. Instruction relating to pneumatics can be extended and reinforced through the use of air-powered tools in power mechanics and automotive mechanics activities.
2. An understanding of how the scientific principles relating to pneumatics are applied can be gained through the disassembly and assembly of air motors or air-powered tools. Emphasis should be placed on understanding the function of the entire unit and the operation of each part in relation to the complete assembly.

Unit 39 — SPRAY GUNS

Compressed air is passed through a tube leading to the nozzle of a spray gun. The rapidly moving air in this tube passes over the open end of another tube which leads from a vented container holding a liquid. The pressure on the open end of the second tube is lowered by the rapid air flow in the first tube. The air pressure on the surface of the liquid in the vented container forces the liquid to flow into the air stream, where it is atomized before reaching the spray nozzle.

A hand-held fly sprayer (with the hand pump to supply the air stream) can be used to demonstrate the principle of operation. The tube supplying the liquid from the vented container is easily seen just in front of the opening from the air pump.

An orderly procedure for the use of a spray gun is given as follows:

1. Inspect all the parts to be sure that they are clean.
2. Reassemble the spray gun.
3. Fill the paint cup with properly thinned and strained paint.
4. Connect the spray gun to the regulator.
5. Set the regulator to the recommended pressure.
6. Test the spray-gun paint pattern on scrap material.
7. Adjust the paint-control valve and air pressure as needed.
8. Hold the nozzle 6 to 12 inches from work.

14669

9. Spray the paint with even, overlapping strokes.
10. Empty the spray gun of unused paint and thoroughly clean the gun and parts in paint thinner.

Scientific Principle Involved: Bernoulli's Principle

When a fluid (gas or liquid) is undergoing a change in velocity, the pressure (measured at right angles to the direction of flow) is lowest at the point of highest velocity. A venturi (constriction) is built into the air tube leading to the nozzle of a spray gun just before the top of the tube from the spray pot. The air must speed up to flow through the venturi, causing a very low pressure as it reaches the top of the paint tube. The air pressure in the vented paint pot forces paint to flow up the paint tube into the air stream, where it is atomized.

Another application of Bernoulli's principle is found in the carburetor of the internal-combustion engine. The air passage through a carburetor is partially constricted at the point where gasoline is mixed with air. This constriction increases the speed of air, lowers its pressure, and permits more rapid evaporation of the gasoline.

Application of Principle

The student will gain valuable experiences and skill in the actual use of a spray gun.

When the trigger of the spray gun is pulled, compressed air travels from the compressor, through the hose and spray gun, and out the nozzle. The air passing through the gun is at its highest velocity at the point where it meets the liquid from the tube of the container. The air pressure at the point where the air and liquid meet is lower than the air pressure in the container. This difference in pressure causes the liquid to rise in the tube and to enter into the air stream. The liquid is atomized and then expelled from the nozzle (DeVilbiss Co.).

Unit 40 — VACUUM PUMPS

Pneumatic power can be produced through the use of compressed air (as explained in Unit 38, "Air-Powered Tools") or a vacuum pump and atmospheric pressure. A vacuum is a positive form of power. The source of this power is the weight of air, which is 14.7 pounds per square inch (psi). To use this power, a vacuum pump must remove the air from one end of a piston so that the air pressure can act on the other end to force it to do work. Vacuum pumps are used in the operation of windshield wipers, power brakes, power clutches, and door locks in the automobile.

Atmospheric pressure is used in the operation of many automotive windshield wipers. The wiper blades are moved by an air-powered motor which uses the pressure differential between the atmospheric pressure and the engine's intake-manifold vacuum for operation. The vacuum is decreased whenever the engine is rapidly accelerated or put under a heavy load. When these conditions occur, the pressure differential disappears, and the air-powered motor no longer has a pressure differential for operation. So that a continuous differential can be provided, a vacuum pump is placed between the windshield-wiper motor and the intake manifold. The vacuum pump maintains a sufficient vacuum (11 inches of mercury; i.e., $5\frac{1}{2}$ pounds below atmospheric pressure) to operate the wiper

14670

motor. Since this vacuum is less than the normal intake-manifold vacuum, the wiper blades operate somewhat more slowly during acceleration and under other conditions requiring maximum engine power. The vacuum pump is an integral part of the fuel pump and operates in an identical manner. (See Unit 35, "Fuel Pumps.") The air flows from the windshield-wiper motor through the vacuum pump into the engine intake manifold. When the engine vacuum is greater than the vacuum developed by the vacuum pump, both the inlet and outlet valves remain open, and the air flows freely from the wiper motor to the manifold. When the manifold vacuum drops, as it does during open throttle and full power operation, the pump acts as a booster, maintaining a minimum vacuum for windshield wiper operation.

Pneumatic systems may be used to multiply a force developed by a man or a machine. An excellent example of a pneumatic power booster is the automobile power-brake system. As vehicle weight, power, and speed are increased, the effort needed to stop the automobile is also increased. The variable factor used to determine the rate of

A combination fuel and vacuum pump shares a common housing and rocker arm (General Motors Corp.).

14671

deceleration is the pressure applied on the brake pedal. So that quicker braking can be done with less movement of the pedal, a pneumatic booster has been added to the system. This booster multiplies the braking force applied to the brake pedal. As a result, a small force applied to the brake pedal provides a high pressure on the hydraulic fluid in the master cylinder that rapidly brings the car to a stop. The power-brake system uses the pressure differential developed by the intake manifold. The booster consists of a chamber, valves, and a piston or diaphragm. Atmospheric pressure is admitted on one side of the diaphragm by the movement of the brake pedal. The intake manifold vacuum on the other side produces a pressure differential on the diaphragm so that the diaphragm moves toward the vacuum. Since the diaphragm is connected directly to the master cylinder, this motion operates the brakes and stops the vehicle. Valves are used to control the braking pressure and to balance the pressure on both sides of the diaphragm when the brakes are released.

Scientific Principle Involved: Atmospheric Pressure

The vacuum pump uses the principle that gas flows from high to low pressure in an attempt to balance the pressure. Atmospheric pressure will pass into the windshield-wiper air motor in its effort to balance the vacuum. The air will then travel to the chamber of the vacuum pump since the action of the diaphragm has reduced the pressure below atmospheric pressure. When the diaphragm moves up on the exhaust stroke, the pressure is increased; thus, a flow of air is produced from the chamber.

Application of Principle

1. A vacuum pump can be disassembled and assembled to determine the principle of operation, the flow of air through the pump, and the function of each part of the pump.
2. Pump operation can be demonstrated by attaching an inflated balloon on the intake side and a deflated baloon on the outlet side. When the pump is operated, the air will move from one balloon to the other.

The schematic of a power brake shows how the control valve (1) can apply either engine vacuum or atmospheric pressure to section (2) of the booster cylinder.

3. Pump operation can be measured by attaching a vacuum gauge to the inlet side of the pump. As the pump is operated by hand, the pressure will drop (the vacuum will increase) to a pressure which counterbalances a mercury column approximately 11 inches high.
4. The force resulting from the operation of a power-brake unit can be determined for a number of different pressure differentials. This determination will require disassembly (or the use of a cutaway). Calculations may also include the mechanical advantage of the master and wheel cylinders in order to determine the available stopping force.
5. A power-brake booster assembly can be disassembled and assembled to determine the function and operation of each part as it contributes to the operation of the power-brake booster assembly.

APPENDIX A

POWER MECHANICS COURSE OUTLINE

In the following relatively brief course outline for industrial arts power mechanics, the topics, where appropriate, are keyed to the instructional units presented in this publication – for example, under "II. A. Muscle Power (Unit 1)"; and to the comprehensive course outline for industrial arts automotive mechanics in Appendix B – for example, under "I. A. Shop/Laboratory Safety (Refer to Appendix B. Section 1, I.)" This power mechanics course outline, when used for a specific course/program, can be expanded by including (1) additional points covered in the designated units; (2) topics presented in the automotive mechanics outline; and/or (3) information from the publications listed under "Selected References" at the end of each unit.

I. Shop/Laboratory Orientation
- A. Shop/Laboratory Safety
  (Refer to Appendix B, Section 1, I.)
  1. General causes of accidents
  2. Personal causes of accidents
  3. Safety instruction
- B. Tools and Equipment
  (Refer to Appendix B, Section 1, II.)
  1. Appreciation of tools
  2. Care of tools
  3. Classification of tools

II. Natural Power
- A. Muscle Power (Unit 1)
  1. Introduction to simple machines
  2. Work, power, energy, force
- B. Waterwheels (Unit 2)
  1. Types: undershot, overshot, breast
  2. Water pressure
- C. Windmills (Unit 3)
  1. Types: multivane, propeller, "S" rotor
  2. Horsepower output of windmill
- D. Heat Collectors (Unit 4)
  1. Conversion of solar energy to electricity
  2. Nature of heat
- E. Solar Stills (Unit 5)

III. Mechanical Power
- A. Simple and Compound Machines (Unit 6)
  1. Mechanical advantage
  2. Lever, wheel and axle, inclined plane, wedge, pulley, screw
  3. Compound machines
- B. Lubrication (Unit 7)
  (Refer to Appendix B, Section 6, I-XVI.)
  1. Viscosity of oils
  2. Lubricating oil functions
  3. Dry, greasy, and viscous friction
- C. Springs (Unit 8)
  (Refer to Appendix B, Section 16, V.)
  1. Classification of springs
  2. Elasticity: Hooke's law
- D. Clutches (Unit 9)
  (Refer to Appendix B, Section 11, I-X.)
  1. Six classifications of clutches
  2. Sliding friction
- E. Dynamometers (Unit 10)
  1. Methods of providing load
  2. Horsepower

IV. Steam Engines
- A. Steam Engines and Turbines (Unit 11)
- B. Conversion of Heat Into Work

V. Thermal Power
- A. High-Energy Rate Forming (Unit 12)
  1. Four methods of forming
  2. Work, power, energy, force
- B. Powder-Actuated Tools (Unit 13)
  1. Precautions to be observed
  2. Expansion of gases
- C. Jet and Rocket Engines (Unit 14)
  1. Types of jet engines
  2. Newton's laws of interactions
- D. Gasoline Testing (Unit 15)
  (Refer to Appendix B, Section 8, IX.)
  1. Power tests
  2. Conversion of chemical energy to heat energy to mechanical energy
- E. Carburetion (Unit 16)
  (Refer to Appendix B, Section 8, VII.)
  1. Carburetor functions
  2. Bernoulli's principle
- F. Two- and Four-Cycle Engines (Unit 17)
  (Refer to Appendix B, sections 3, 4, 5.)
  1. Four-stroke cycle
  2. Two-stroke cycle
  3. Expansion of gases
- G. Wankel Engines (Unit 18)
  1. Rotor-type engine
  2. Moment of inertia

14676

H. Thermostats (Unit 19)
(Refer to Appendix B, Section 7, VIII.)
1. Types and purposes
2. Thermal expansion

I. Welding Processes (Unit 20)
1. Gas, arc, and resistance welding
2. Kinetic molecular theory

VI. Electrical Power

A. Dry Cells: Primary Cells (Unit 21)
1. Zinc-carbon and mercury cells
2. Conversion of chemical energy into electrical energy

B. Storage Batteries: Secondary Cells (Unit 22)
(Refer to Appendix B, Section 9, IV.)
1. Conversion of chemical energy into electrical energy
2. Electrolysis
3. Hydrometer test
4. Specific gravity
5. Battery installation and servicing
6. Corrosion and oxidation of metals
7. Battery testing
8. Capacity rating of batteries
9. Battery charging
10. Chemical change in lead-acid storage cell

C. Generation of Electricity (Unit 23)
1. Magnetos
2. Magnetism
3. Direct-current generators and alternators
4. Electromagnetic induction
5. Alternating-current rectifiers
6. Rectification of current
7. Generator regulation
8. Electromagnetic switch

D. Transmission of Electric Power (Unit 24)
(Refer to Appendix B, Section 9, III.)
1. Electromotive force
2. Conductors and insulators
3. Electron theory
4. Voltage, current, and resistance
5. Ohm's law
6. Series and parallel circuits
7. Direct-current circuits

E. Transformers (Unit 25)
1. Types: step-up, step-down
2. Electromagnetic induction

F. Spark Plugs (Unit 26)
(Refer to Appendix B, Section 9, IX.D.)
1. Heat-range classification
2. Ionization of gases

G. Ignition Systems (Unit 27)
(Refer to Appendix B, Section 9, IX.)
1. Conventional and transistorized systems
2. Electromagnetic energy

H. Electric Motors (Unit 28)
(Refer to Appendix B, Section 9, V.)
1. Motors: series and shunt wound
2. Electromagnetic induction

I. Fuel Cells (Unit 29)
1. Use in spacecraft
2. Electrochemical effect

J. Photoelectric Cells (Unit 30)
1. Types and uses
2. Photoelectric effect

K. Semiconductor Power Rectifiers (Unit 31)
1. Types of rectifiers
2. P- and N-type semiconductors

VII. Hydraulic Power

A. Jacks and Presses (Unit 32)
1. Hydraulic pump components
2. Pascal's principle

B. Machine Tools (Unit 33)
1. Efficiency of hydraulic systems
2. Pressure transmission by liquids

C. Braking Systems (Unit 34)
(Refer to Appendix B, Section 20, I-VII.)
1. Devices for retarding or stopping motion
2. Pascal's principle

D. Fuel Pumps (Unit 35)
(Refer to Appendix B, Section 8, VI.)
1. Positive displacement pump
2. Atmospheric pressure

E. Power Steering (Unit 36)
(Refer to Appendix B, Section 17, VII.)
1. Advantage of power steering
2. Pressure transmission by liquids

F. Air Conditioners (Unit 37)
1. Types of air conditioners
2. Heat transfer

VIII. Pneumatic Power

A. Air-Powered Tools (Unit 38)
1. Piston and rotary-vane motors
2. Mechanical properties of gases

B. Spray Guns (Unit 39)
1. Operation and procedure for use
2. Bernoulli's principle

C. Vacuum Pumps (Unit 40)
1. Windshield wipers
2. Power brakes
(Refer to Appendix B, Section 20, IV.)
3. Balancing effect of atmospheric pressure

14677

APPENDIX B

AUTOMOTIVE MECHANICS COURSE OUTLINE

Section 1: Shop/Laboratory Practice

I. Automotive Shop/Laboratory Safety
- A. General Causes of Accidents
  1. Improper attitude
     - a. Disregard for rules of safety
     - b. Recklessness
     - c. Laziness
     - d. Uncooperativeness
     - e. Fearfulness
     - f. Impatience
     - g. Lack of consideration
     - h. Immaturity
  2. Lack of knowledge or skill
     - a. Lack of understanding what is to be done
     - b. Lack of conviction of need for following prescribed procedures
- B. Personal Causes of Accidents
  1. Operating equipment without permission
  2. Neglecting to secure assistance when needed
  3. Failing to warn other people about unsafe practices or equipment
  4. Operating equipment at unsafe speeds
  5. Working too fast
  6. Neglecting to use safety devices
  7. Using hands instead of equipment for holding material
  8. Assuming an unsafe position or posture
  9. Working unsafe equipment
  10. Distracting, teasing, abusing, and startling others
  11. Failing to use proper clothing and protective gear
- C. (Refer to *Industrial Arts Safety Instruction*, published by the California State Department of Education, as well as safety instructions issued by the offices of county superintendents of schools and by school districts.)

II. Automotive Tools and Power Equipment
- A. Appreciation of Tools
  1. Development
  2. Value to society
- B. Care of Tools
  1. Storage of tools
  2. Maintenance
     - a. Sharpening
     - b. Lubricating
     - c. Repairing

  (Report tools in need of repair.)
- C. Classification of Automotive Tools
  1. Chisels
     - a. Cape
     - b. Cold
     - c. Diamond-point
     - d. Half-round
     - e. Roundnose
  2. Drilling tools
     - a. Hand drill
     - b. Electric drill
     - c. Twist drill
     - d. Reamers
  3. Files
     - a. Mill
     - b. Taper
     - c. Square
     - d. Round
     - e. Half-round
     - f. Breaker-point
     - g. Vixen-cut (body)
  4. Hammering tools
     - a. Ball peen hammer
     - b. Rawhide-faced mallet
     - c. Plastic-tipped mallet
     - d. Brass mallet
     - e. Rubber mallet
     - f. Sledgehammer
     - g. Dinging hammer
  5. Measuring tools
     - a. Feeler gauges
     - b. Micrometers
     - c. Steel rules
  6. Pliers
     - a. Slip-joint (combination)
     - b. Diagonal (cutting)
     - c. Long-nose (needle-nose)
     - d. Round-nose
     - e. Pump-type (channel-lock)
     - f. Side-cutting (electrician's)
     - g. Vise-grip
     - h. Brake-spring
     - i. Hose-clamp
  7. Punches
     - a. Aligning
     - b. Center
     - c. Pin
     - d. Starting
  8. Hacksaw

14678

9. Screwdrivers
   a. Standard-tipped
   b. Phillips
   c. Clutch
   d. Offset
   e. Setscrew driver (Allen wrench)
10. Shearing tools
   a. Straight shears
   b. Combination shears
   c. Duckbill shears
   d. Multileverage (aviation) shears
11. Soldering tools
   a. Soldering copper
      (1) Standard
      (2) Electric
   b. Fluxes
12. Threading tools
   a. Taps
      (1) Taper
      (2) Plug
      (3) Bottoming
      (4) Machine screw
   b. Dies
13. Wrenches and handles
   a. Open-end wrench
   b. Box-end wrench
   c. Socket wrench
      (1) Standard
      (2) Deep
      (3) Universal
   d. Torque wrench
   e. Adjustable-end wrench
   f. Monkey wrench
   g. Pipe wrench
   h. Handles
      (1) Speed (spinner)
      (2) Ratchet
      (3) Flex (break-over)
      (4) Tee
   i. Extensions
14. Specialized tools
   a. Pneumatic
   b. Hydraulic
   c. Electrical testing
   d. Engine and accessories' testing
   e. Body and fender
15. Power equipment
16. Welding equipment

Section 2: Automobile Components

I. Automobile Components
   A. Engine
   B. Framework
   C. Power Train
   D. Body
   E. Accessories

II. Engine
   A. Purpose
   B. Types
      1. Internal combustion
      2. External combustion
   C. Systems
      1. Fuel system
         a. Purpose
         b. Components
            (1) Fuel tank and lines
            (2) Fuel filter
            (3) Air cleaner (wet and dry)
            (4) Fuel pump
            (5) Carburetor
            (6) Fuel injectors
            (7) Intake manifold
            (8) Fuel-level indicator
      2. Ignition system
         a. Purpose
         b. Components
            (1) Battery (6 or 12 volts)
            (2) Distributor
            (3) Magneto
            (4) Coil
            (5) Spark plugs
            (6) Ignition switch
            (7) Wiring
      3. Lubrication system
         a. Purpose
         b. Components
            (1) Oil pump
            (2) Oil filter
            (3) Oil galleries and passages
            (4) Oil-pressure indicator
            (5) Crankcase
            (6) Crankcase ventilator
      4. Cooling system
         a. Purpose
         b. Types
            (1) Liquid-cooled
            (2) Air-cooled
         c. Components
            (1) Radiator
            (2) Fan blade
            (3) Water pump
            (4) Water jackets and passages
            (5) Thermostat
            (6) Temperature indicator
      5. Electrical system
         a. Purpose
         b. Components
            (1) Battery
            (2) Regulator
            (3) Generator/alternator
            (4) Starting motor
            (5) Wiring
            (6) Switches
            (7) All activated components

14679

III. Framework
- A. Purpose
- B. Construction
  - 1. Box type
  - 2. X-type
  - 3. Unitized type
- C. Units Attached to Framework
  - 1. Engine
  - 2. Suspension system (front and rear)
    - a. Springs
      - (1) Purpose
      - (2) Types
        - (a) Coil
        - (b) Laminated leaf
        - (c) Single leaf
        - (d) Torsion bar
        - (e) Air suspension
    - b. Shock absorbers
      - (1) Purpose
      - (2) Type: direct-acting, telescoping
    - c. Steering system: purpose
    - d. Brakes
      - (1) Purpose
      - (2) Types
        - (a) Mechanical
        - (b) Hydraulic
        - (c) Pneumatic
        - (d) Electric
        - (e) Rigid or independent
      - (3) Components
        - (a) Brake-pedal assembly
        - (b) Master-cylinder assembly
        - (c) Brake lines
        - (d) Wheel-cylinder assemblies
        - (e) Wheel-brake assemblies
        - (f) Hand brake
      - (4) Principle of operation
      - (5) Power brakes
    - e. Tires
      - (1) Purpose
      - (2) Types
        - (a) Tube-type
        - (b) Tubeless
      - (3) Classification
        - (a) Size
        - (b) Plies
        - (c) Material

IV. Power Train
- A. Purpose
- B. Components
  - 1. Clutch
    - a. Purpose
    - b. Types commonly used
      - (1) Single dry disk
      - (2) Fluid coupling
  - 2. Transmission
    - a. Purpose
    - b. Types
      - (1) Standard: manual shift
      - (2) Automatic
      - (3) Overdrive
  - 3. Propeller shaft: purpose
  - 4. Differential
    - a. Purpose
    - b. Gear ratio
  - 5. Rear axles
    - a. Purpose
    - b. Types
      - (1) Live: rear
      - (2) Dead: front

V. Body
- A. Purpose
- B. Design (streamlining)
- C. Construction
  - 1. Pressed-steel panels
  - 2. Reinforcing members
  - 3. Attaching brackets
  - 4. Attaching bolts (rubber-mounted)
- D. Components
  - 1. Firewall assembly
  - 2. Instrument-panel assembly
  - 3. Floor assembly
  - 4. Roof assembly
  - 5. Doors- and center-pillar assembly
  - 6. Rear-quarter assemblies
  - 7. Rear-end assembly
  - 8. Front fenders, hood, and grill assembly
  - 9. Windshield and glass assemblies
  - 10. Seats
  - 11. Body-ventilating system
  - 12. Headlining assembly
  - 13. Exterior molding and trim
- E. Finishes
- F. Body Styles
  - 1. Sports coupe and sedan
  - 2. Convertible
  - 3. Sedans
  - 4. Station wagons
  - 5. Sports cars
  - 6. Compacts
  - 7. Sports wagons (buses, others)
  - 8. Pick-up trucks, trucks (assorted sizes and uses)

VI. Accessories
- A. Definition
  - 1. Comfort/convenience
  - 2. Safety and safety belts
- B. Examples
  - 1. Radio
  - 2. Heater, defroster, air conditioner
  - 3. Windshield wiper
  - 4. Clock
  - 5. Back-up lights
  - 6. Spotlight

1814680

7. Courtesy light
8. Automatic light-dimmer

Section 3: Types of Engines

I. Purpose of Engine Classification
   A. To Differentiate Between Engines for Clear Communication
   B. To Categorize Engines by Common General Features
   C. To Describe Engines for Information and Possible Application

II. Criteria for Engine Classification
   A. Types of Fuel
      1. Gasoline (high and low compression)
      2. Fuel oil (diesel, Hesselman)
      3. Liquefied petroleum gas (LPG)
   B. Cycling
      1. Four-stroke cycle
      2. Two-stroke cycle
   C. Cooling
      1. Liquid-cooled
      2. Air-cooled
      3. Combined
   D. Valve Arrangement
      1. L-head (flat head)
      2. I-head (overhead valve)
      3. F-head (combination L- and I-head)
      4. T-head
   E. Cylinders
      1. Number of cylinders
      2. Arrangement of cylinders
         a. Inline
            (1) Vertical
            (2) Inverted
            (3) Slant or tilt
         b. Vee
            (1) Vertical
            (2) Inverted
            (3) Variable angle
         c. Opposed (pancake)
         d. Radial
            (1) Single bank
            (2) Multibank
         e. Rotary Wankel
   F. Use
      1. Passenger car
      2. Truck or bus
      3. Agricultural machinery
      4. Construction equipment
      5. Aircraft
      6. Motorcycles
      7. Railroad engines
      8. Marine
      9. Stationary
      10. Specialized use
   G. Identification
      1. Manufacturer's name
         a. Real manufacturer: Ford, General Motors, others
         b. Application manufacturer: International Harvester, Gillig, Euclid, others
      2. Designer's name
         a. Individual designer: Diesel, Wankel, others
         b. Multiple designer: Pratt and Whitney, others
      3. Series number (390, F100, 300G, others)
   H. Additional Types and Innovations
      1. Turbojet
      2. Ramjet
      3. Gas turbine
      4. Free piston
      5. NSU-Wankel
      6. Rocket
      7. Fuel cell
      8. Solar
      9. Electric
      10. Steam

Section 4: Engine Operation and Measurement

I. Physical Principles Related to Engine Operation
   A. Definition of Physical Principles
   B. Structure of Matter
      1. Atoms
         a. Size
         b. Structure
            (1) Electrons
            (2) Protons
            (3) Neutrons
      2. Elements
      3. Molecules
         a. Structure
         b. Chemical reaction
   C. States of Matter
      1. Liquids
      2. Solids
      3. Gases
   D. Combustion
      1. Definition
      2. Products of combustion
         a. Heat
         b. Light
         c. By-products
   E. Heat
   F. Change of State
      1. Definition
      2. Method of accomplishment
         a. Application of heat
         b. Application of cold
   G. Expansion of Matter
      1. Liquids: thermometer
      2. Solids: thermostat
      3. Gases: combustion chamber

0814681

H. Pressure Increase
  1. Cause
  2. Results
    a. Temperature increase
    b. Compression
I. Gravity
  1. Definition
  2. Measurement: weight
J. Atmospheric Pressure
  1. Definition
  2. Weight of air
  3. Pressure exerted
K. Vacuum
  1. Definition
  2. "Partial vacuum"

II. Engine Operation
A. Cylinder Design
  1. Description
  2. Sealing
    a. Head
    b. Valves
B. Piston
  1. Description
  2. Piston fit
  3. Materials used
  4. Piston action
    a. Combustion
    b. Heat
    c. Pressure increase
C. Piston Rings
  1. Purpose
  2. Location
  3. Types
D. Valves
  1. Type
  2. Purpose
  3. Ports
    a. Intake
    b. Exhaust
  4. Valve operating mechanism
    a. Camshaft
    b. Cam followers or lifters
    c. Pushrods
    d. Valve spring
    e. Rocker arm
E. Crankshaft
  1. Purpose
  2. Description
  3. Rotary motion
F. Action in Cylinder
  1. Definition of "stroke"
    a. BDC to TDC
    b. TDC to BDC
  2. Four-stroke cycle
    a. Two crankshaft revolutions
    b. Four strokes
      (1) Intake
      (2) Compression
      (3) Power
      (4) Exhaust
  3. Two-stroke cycle
  4. Diesel engines
G. Flywheel
  1. Description
  2. Purpose

III. Forces
A. Work
  1. Definition
  2. Illustrations
  3. Measure in terms of distance and force
  4. Formula: $Work = f \times d$
B. Energy
  1. Definition
  2. Potential
  3. Kinetic
C. Power
  1. Definition
  2. High-powered machine
  3. Low-powered machine
  4. Horsepower
    a. Definition
    b. Formula: $Hp = \frac{force \times distance}{33{,}000 \times time}$
D. Inertia
  1. Definition
  2. Evidence of inertia at work
E. Torque
  1. Definition
  2. Method of measure (foot-pounds)
  3. Formula: *Torque = force × distance (lever arm)*
F. Friction
  1. Definition
  2. Types
    a. Dry
    b. Viscous
    c. Greasy

IV. Engine Measurements
A. Bore
  1. Definition
  2. Method of determination
B. Stroke
  1. Definition
  2. Method of determination
C. Piston Displacement
  1. Definition
  2. Formula: $Displacement = \frac{\pi D^2 L}{4}$
  3. Multicylinder total displacement × number of cylinders
D. Compression Ratio
  1. Definition
  2. Clearance volume
  3. Formula: *Cylinder volume @ BDC ÷ clearance volume*
  4. Problem related to higher compression ratios

14682

a. Power increase
b. Predetonation more acute (knocking)

V. Engine Power Output
A. Brake Horsepower (bhp)
1. Definition
2. Prony brake test
B. Indicated Horsepower (ihp)
1. Definition
2. Oscilloscope test
C. Friction Horsepower (fhp)
1. Definition
2. Method of determination
D. SAE Horsepower
1. Definition
2. Purpose
E. Engine Torque
1. Definition
2. Method of determination

VI. Engine Efficiency
A. Mechanical Efficiency
1. Relationship between bhp and ihp
2. Formula: *ME = bhp ÷ ihp (answer in percent)*
B. Thermal Efficiency
1. Relationship between power output and energy in fuel burned
2. Heat losses
a. Cooling by water and oil (35 percent)
b. Lost in exhaust gases (35 percent)
3. Limitations to thermal efficiency
a. Excessive heat
b. Breakdown in lubrication system
C. Volumetric Efficiency
1. Relationship between amount of fuel-air mixture actually entering cylinder and amount that could enter
2. Factors affecting volumetric efficiency
a. Engine rpm
b. Temperature of fuel-air mixture

VII. Overall Efficiency
A. Rolling Resistance
B. Air Resistance
C. Acceleration (overcoming of inertia)

Section 5: Engine Construction

I. Manifolds
A. Methods of Manufacture
1. Materials used
2. Design
B. Intake Manifold
1. Purpose
2. Types
3. Location
C. Exhaust Manifolds
1. Purpose
2. Types
3. Location
4. Manifold heat-control valve
D. Manifold Inspection
1. Check for warpage
2. Check for cracks
3. Check surface
4. Check heat-control valve for freeness

II. Cylinder Head
A. Methods of Manufacture
1. Materials used
2. Design
B. Types
1. Valve-in-head
2. Flat head
C. Purpose
1. Combustion chamber
2. Water jackets
3. Intake and exhaust ports and passages
D. Rocker-Arm Cover

III. Oil Pan
A. Methods of Manufacture
1. Materials used
2. Design
B. Purpose
1. Baffles
2. Oil troughs
3. Nozzles
4. Drain plug
5. Seals
C. Oil Pump
1. Purpose
2. Types
a. Gear
b. Dual rotor
3. Location
4. Oil intake
5. Screen

IV. Valve Train
A. Camshaft
1. Methods of manufacture
2. Purpose
3. Types
a. Stock
b. Other grinds
4. Location
5. Components
a. Cam lobes
b. Fuel pump eccentric
c. Distributor drive gear
d. Bearing journals
e. Thrust plate
6. Camshaft timing gear or sprocket
7. Timing chain
B. Valve Lifters (Tappets)
1. Purpose
2. Location
a. I-head

14083

PATTERN ADJUSTMENT FOR BROAD SHOULDERS

Diagram shows wrinkles and distortion of grain line on back of ill fitting garment caused by narrow shoulders.

Diagram shows bodice back and front pieces altered by splitting and spreading patterns at shoulder to create new shoulder and armscye lines.

BBL
50
1465

b. L-head
c. F-head
3. Types
a. Solid
b. Adjustable
c. Hydraulic

C. Push Rod
1. Purpose
2. Location
3. Types
a. Tubular
b. Solid

D. Rocker Arm and Shaft
1. Purpose
2. Rocker-arm types
a. Cast
b. Forged
c. Stamped steel
3. Rocker-arm shaft
a. Location
b. Purpose

E. Valve Guides
1. Purpose
2. Location
3. Types
a. Pressed in
b. Slip in
c. Integral
4. Lifter guides

F. Valves
1. Methods of manufacture
2. Purpose
a. Intake
b. Exhaust
3. Types (past and present)
a. Rotary
b. Sliding-sleeve
c. Poppet or mushroom
4. Parts of poppet valve
a. Head
b. Margin
c. Face
d. Neck
e. Stem
f. Spring-retainer lock groove
g. Tip
5. Valve cooling
a. Purpose
b. Method
(1) Water jackets
(2) Water-distributing tube
c. Sodium valves
6. Valve seat
a. Purpose
b. Types
(1) Direct
(2) Inserts

G. Valve Springs
1. Purpose
2. Types
a. Single
b. Double
3. Retainers
a. Stationary
b. Free type
c. Positive type
4. Retainer locks (keepers)
a. Conical
b. Pin
c. Horseshoe

H. Relationship of Parts in L-Head Engine
I. Relationship of Parts in I-Head Engine
J. Relationship of Parts in F-Head Engine

V. Piston and Connecting Rod Assembly

A. Piston
1. Methods of manufacture
2. Purpose
3. Parts of piston
a. Head
b. Ring grooves
c. Ring lands
d. Pin boss and bushing
e. Skirt
(1) Major thrust face
(2) Minor thrust face
4. Expansion control
a. Steel rings
b. Struts
c. Slots
d. Cam ground pistons

B. Piston Rings
1. Methods of manufacture
2. Purpose
a. Seal compression
b. Control oil
3. Types
a. Compression
(1) Plain
(2) Tapered
(3) Grooved
b. Oil control
4. Ring joints
a. Types
(1) Butt
(2) Angle
(3) Lap
b. Ring gap
5. Ring expanders
a. Purpose
b. Location
6. Coated rings
7. Chrome-plated rings

C. Piston Pin
1. Purpose

14684

2. Types
   a. Center-lock
   b. End-lock
   c. Slotted
   d. Press-fit
   e. Floating
D. Connecting Rod
   1. Purpose
   2. Method of manufacture
   3. Parts
      a. Rod
      b. Little end (bushing)
      c. Big end
      d. Rod cap
      e. Oil holes
      f. Rod nuts
         (1) Safe wire
         (2) Self-locking
         (3) Cotter pin
         (4) Palnut
      g. Tongue and groove
   4. Rod stretch and reconditioning
   5. Alignment of oil holes

VI. Bearings
A. Methods of Manufacture
B. Purpose
C. Types
   1. Bushings
   2. Sleeve
   3. End thrust
   4. Poured
   5. Semi-fitted
   6. Precision insert: types of metal overlays
   7. Roller
   8. Ball
D. Location
   1. Main bearings
   2. Connecting-rod bearings
   3. Camshaft bushings
   4. Piston pin bushings
   5. Clutch pilot-bushing or -bearing
   6. Camshaft thrust plate
E. Oil Clearance
F. Requirements
   1. Load-carrying capacity
   2. Fatigue resistance
   3. Embeddability
   4. Conformability
   5. Corrosion resistance
   6. Low wear rate

VII. Crankshaft
A. Methods of Manufacture
   1. Materials used
   2. Design
B. Purpose
   1. Connecting rod throws
   2. Main bearing journals
   3. Counterbalances
   4. Oil passages
   5. Oil slinger/thrust pad
C. Flywheel
   1. Purpose
      a. Supplies inertia to crankshaft
      b. Engages with starter motor
      c. Driving member of clutch
   2. Location
D. Crankshaft Timing-Gear or Sprocket
E. Vibration Damper
   1. Purpose
   2. Construction
   3. Location

VIII. Cylinder Block
A. Methods of Manufacture
   1. Materials used
   2. Design
B. Purposes
   1. Cylinders
   2. Water jackets
   3. Welch plugs (soft plugs)
   4. Intake and exhaust ports and passages
   5. Valve-lifter chamber
   6. Oil galleries
   7. Pressure relief valve
C. Engine Serial Number Location

IX. Gaskets
A. Materials Used
   1. Soft metal
   2. Fiber
   3. Rubber
   4. Neoprene
   5. Cork
   6. Leather
B. Purpose
C. Types and Location
   1. Cylinder head
   2. Oil pan
   3. Push-rod cover
   4. Valve cover
   5. Manifolds
   6. Timing-gear cover and seal
   7. Main bearing seal

X. Miscellaneous Components
A. Bell Housing
   1. Purpose
   2. Dust cover
B. Engine Mounts

Section 6: Engine Lubrication System

I. Purpose of Lubrication System
A. Lubricate Moving Parts to Prevent Wear
B. Lubricate Moving Parts to Reduce Power Loss from Friction
C. Act as Cooling Agent

14685

D. Absorb Shock Between Bearings and Other Moving Parts
E. Form Seal Between Piston Rings and Cylinder Walls
F. Act as Cleaning Agent

II. Theory of Lubrication
A. Friction Bearings
B. Antifriction Bearings
C. Oil Passages
1. Circulation
2. Location
a. Internal
b. External

III. Source of Oil
A. History and Development
1. Discovery
2. Early uses
3. Oil and automobile
B. Modern Processes
1. Modern oil fields
2. Refining

IV. Properties of Oil
A. Viscosity
1. Body
2. Fluidity
B. Viscosity Ratings
1. Viscosimeter
2. Temperature
C. Viscosity Index
D. Resistance to Carbon Formation
E. Additives
1. Oxidation inhibitors
2. Antifoam agents
3. Detergents
4. Antiwear additives
5. Acid inhibitors
6. Varnish inhibitors
7. Sludge inhibitors

V. Water Sludge Formation
A. Process of Formation
B. Prevention of Sludge
1. Types of car opefation
2. Temperature
3. Crankcase ventilating system

VI. Service Ratings of Oil (API)
A. MS
B. MM
C. ML
D. DS
E. DG

VII. Oil Changes
A. Purpose
1. Replace contaminated oil
2. Keep engine clean
3. Drain oil
a. From below
b. From above
B. Oil Change Interval
1. Factory recommendations
a. For engine with oil filter
b. For engine without oil filter
2. Other recommendations

VIII. Oil Consumption
A. Causes
1. Engine condition
2. Driving conditions
3. Mixture of oil types
B. Corrections

IX. Types of Lubrication Systems
A. Splash
B. Pressure Feed
C. Combination of Splash and Pressure Feed

X. Oil Pumps
A. Purpose: Circulation
B. Location
1. Internal
2. External
C. Types
1. Gear
2. Dual rotor
3. Vane
4. Plunger
D. Theory of Operation
1. Capacity
2. Priming
E. Method of Drive
1. Distributor
2. Cam gear
3. Crankshaft gear
F. Parts
1. Camshaft gear
2. Shaft
3. Body
4. Drive gear
5. Idler gear
6. Cover
7. Intake
8. Outlet
9. Screen

XI. Relief Valves
A. Purpose
B. Types
1. Plunger
2. Ball
C. Location
1. Block
a. Internal
b. External
2. Pump
D. Operation

XII. Oil Filters
A. Purpose
B. Location

14686

C. Types
  1. By-pass
  2. Full-flow
D. Theory of Operation
E. Change Interval

XIII. Oil Coolers
A. Purpose
B. Types
C. Location
D. Operation
E. Transference of Heat

XIV. Oil-Pressure Indicators
A. Purpose
B. Location
  1. Dash unit
  2. Engine sender unit
C. Types
  1. Bourdon tube
  2. Electric
    a. Balancing coil
    b. Bimetal
    c. Warning light

XV. Crankcase Ventilation
A. Purpose
B. Types
  1. Standard
  2. Positive
C. Operation
D. Smog Control

XVI. Oil-Level Indicators
A. Purpose
B. Location

Section 7: Engine Cooling System

I. Purpose of Engine Cooling System
A. Maintain Efficient Engine Operating Temperature
B. Regulate Engine Operating Temperature to Driving Conditions
C. Maintain Temperature Limits
  1. Results of overheating
    a. Breakdown of lubrication oil
    b. Damage to bearing and moving parts
    c. Warpage and cracking of cylinder head
    d. Loss of coolant
    e. Stoppage of water circulation
    f. Changes in clearance
  2. Results of overcooling
    a. Loss of engine thermal efficiency
    b. Excessive consumption of fuel
    c. Dilution of engine oil
    d. Formation of sludge
      (1) Lubrication failure
      (2) Corrosive acids
    e. Changes in clearance

II. Types of Cooling Systems
A. Air-Cooled
  1. Cooling fins
  2. Circulation of air
B. Liquid-Cooled
  1. Thermosyphon
    a. Gravity
    b. Natural laws of water circulation (convection)
  2. Forced circulation
    a. Method of circulation
    b. Circulation under pressure

III. Four Essentials of Cooling System
A. Absorption
B. Circulation
C. Radiation
D. Control

IV. Water Jackets
A. Cylinder Block
B. Cylinder Head
C. Water-Distribution Tubes
D. Water Nozzles
E. Soft Plugs (Welch Plugs)

V. Water Pump
A. Purpose
B. Type Used
C. Location
D. Parts
  1. Housing
  2. Water inlet
  3. Water outlet
  4. Impeller
  5. Shaft
  6. Seals
  7. Pulley
  8. Bearings
E. Theory of Operation
F. Method of Drive

VI. Engine Fan
A. Purpose
B. Location
C. Method of Drive

VII. Radiator
A. Purpose
B. Compartments
  1. Air passages
  2. Water passages
C. Radiator Types
  1. Ribbon cellular
  2. Tube and fin
D. Radiator Parts
  1. Radiator shell
  2. Radiator core
    a. Top header
    b. Water tubes
    c. Air fins

14686

14687

3. Fan shroud
4. Shell attaching bolts
5. Water inlet
6. Water outlet
7. Upper tank
8. Lower tank
9. Connecting hoses
10. Drain cock

E. Draining Radiator
1. With pressure cap
2. Without pressure cap

VIII. Thermostats
A. Purpose
B. Location
1. Water-cooled
2. Air-cooled
C. Types
1. Bellows
2. Bimetallic
3. Solid expansion
D. Thermostat Parts
1. Case
2. Bellows or spring
3. By-pass valve
4. Air-bleed hole
E. Principles of Operation
1. Temperature ranges
2. Water circulation: cold
3. Water circulation: hot

IX. Radiator Pressure Cap
A. Purpose
1. Improve cooling efficiency
2. Prevent evaporation
3. Prevent surge losses
B. Physical Principles
1. Pressure increase
2. Boiling-point effects
C. Pressure Cap Parts
1. Vacuum valve
2. Blowoff valve
3. Overflow pipe
D. Pressure Cap Capacities

X. Temperature Indicators
A. Purpose
B. Location
1. Dash unit
2. Engine unit
C. Indicator Types
1. Vapor pressure
2. Electrical
a. Balancing coil
b. Bimetal thermostat

XI. Antifreeze Solutions
A. Purpose
B. Physical Principles
1. Freezing: expanding force
2. Prevention of freezing
C. Requirements for Good Antifreeze Solution
1. Mixes readily with water
2. Circulates freely
3. Must not damage system by corrosion
4. Must not freeze
D. Inadequate Antifreeze Solutions
1. Salt solutions
2. Sugar solutions
3. Oil products
4. Kerosene
5. Glycerin
E. Temporary Antifreeze Solutions
1. Alcohol
2. Alcohol base materials
a. Low boiling point
b. Evaporation
F. Permanent Antifreeze Solutions
1. Ethylene glycol materials: percentages
2. Methanol materials: percentages

XII. Radiator Additives
A. Cooling System Cleaners
B. Sealer
C. Acid and Rust Inhibitor

XIII. Special Features
A. Surge Tank
B. Radiator Covers
C. Radiator Screens

XIV. Hot-Water Car Heater
A. Purpose
B. Parts
1. Heater radiator
2. Fan motor
3. Fan blades
4. Connecting hoses
C. Theory of Operation

Section 8: Engine Fuel System

I. Purpose of Engine Fuel System
A. Store Fuel
B. Deliver Fuel to Engine
C. Mix Fuel and Air to Proper Proportions

II. History and System Types
A. Gravity Feed System
1. Tank located higher than carburetor
2. System used about 1900 to 1931
B. Vacuum System
1. Vacuum tank located higher than carburetor
2. Intake-manifold vacuum applied to vacuum tank
3. Gravity from vacuum tank to carburetor
4. System invented about 1920
C. Pressure System
1. Fuel tank under 2 to 4 pounds higher pressure than atmospheric
2. Hand pump on dash for starting

14688

3. Engine pump used after running
4. System used in some higher-priced cars about 1915

D. Propane and Butane Systems
1. Creates own pressure
2. Stored as a liquid
3. Released as a vapor
4. Used in localities where readily available
5. Used now on some installations

E. Pump System
1. Draws from tank by vacuum
2. Forces to carburetor by pressure
3. Now standard type of installation

III. Fuel Tanks
A. Purpose
B. Location
C. Structure
1. Metal: spark proof
2. Corrugation
3. Baffles
4. Filler pipe
5. Filler cap
6. Vent
7. Gauge sending-unit location
8. Fuel line
9. Filter screen
10. Drain plug

IV. Fuel-Level Indicators
A. Purpose
B. Types
1. Stick
2. Hydrostatic
3. Mechanical
4. Electric
a. Bimetal type
b. Balancing coil type

V. Fuel Lines
A. Purpose
B. Types
1. Steel
2. Copper
3. Flexible
C. Fittings
1. Compression
2. Flared
D. Location
1. Vibration
2. Sharp edges
3. Heat

VI. Fuel Pumps
A. Purpose
B. Location
C. Diaphragm Types
1. Bellows
2. Plunger
3. Impeller
4. Combination
D. Operation

VII. Carburetion
A. Carburetor Fundamentals
1. Purpose of carburetor
2. Physical principles
a. Atmospheric pressure
b. Vacuum
c. Evaporation
d. Atomization
B. Carburetor Basic Parts
1. Air horn
2. Venturi
3. Fuel nozzle
4. Throttle valve
C. Fuel Mixtures
1. Rich
a. Ratio
b. Conditions when needed
2. Lean
a. Ratio
b. Conditions when needed
D. Float Circuit
1. Purpose
2. Operation
3. Fuel-pump control
a. Leverage
b. Hydraulics of surface areas
4. Concentric
a. Horseshoe float
b. Dual-float assembly
5. Dual-float circuits
6. Float-bowl vent
a. Balanced
b. Unbalanced
7. Air bleed: purpose
8. Adjustment
a. Fuel level too low
b. Fuel level too high
E. Idle- and Low-Speed Circuit
1. Purpose
2. Operation
a. Air-horn conditions
b. Idle circuit
c. Low-speed circuit
d. Air bleeds
3. Adjustment
a. Idle speed
b. Idle mixture
F. High-Speed Part-Load Circuit
1. Purpose
2. Operation
a. Mechanical (metering rod)
b. Vacuum (power valve)
G. High-Speed Full-Power Circuit
1. Purpose

14589

2. Operation
   a. Mechanical (metering rod)
   b. Vacuum (power valve)
   c. Combination mechanical and vacuum

H. Accelerator-Pump Circuit
1. Purpose
2. Operation
   a. Plunger
   b. Diaphragm
3. Adjustment

I. Choke Circuit
1. Purpose
2. Manual operation
3. Vacuum operation
4. Electric
5. Adjustment

J. Other Carburetor Features
1. Throttle cracker
2. Fast idle
3. Antipercolator
4. Throttle-return checks
   a. Dashpot
   b. Diaphragm
5. Distributor-vacuum circuit
6. Starter switches
7. Kick-down switches
8. Governors

K. Carburetor Types
1. Fuel entry to manifold
   a. Downdraft
   b. Updraft
   c. Side draft
2. Barrels
   a. Single barrel
   b. Two barrel
   c. Four barrel
      (1) Primaries
      (2) Secondaries
      (3) Progressive linkage
      (4) Circuit variations from single and two barrel
3. Multiple carburetors
   a. Two two-barrels
   b. Three two-barrels
   c. Two four-barrels
      (1) Unison linkage
      (2) Progressive linkage
      (3) Vacuum-controlled linkage
4. Fuel injection
   a. Combustion chamber
   b. Intake manifold

VIII. Air Cleaners
A. Purpose
B. Oil-Bath Type
1. Operation
2. Service
C. Dry Type
1. Operation
2. Service

IX. Fuels
A. Fuels in General Use
1. Gasoline
2. Benzene
3. Benzol
4. Alcohol
5. Natural gas
6. Fuel oil
7. Propane and butane

B. Physics of Carburetion and Combustion of Gasoline
1. Combustion
2. Compression
3. Fuel knock (detonation and preignition)
   a. Heat on irregular surfaces
   b. Compression ratio
   c. Ignition timing
   d. Rapid burning
      (1) Antiknock value
      (2) Measurement of antiknock value
      (3) Chemical control
      (4) Weight of air
      (5) Vaporization
         (a) Spraying
         (b) Heat
         (c) Vacuum
      (6) Volatility
         (a) Starting
         (b) Vapor lock
         (c) Warm-up
         (d) Acceleration
         (e) Economy
         (f) Crankcase dilution
         (g) Evaporation during nonoperation
         (h) Atmospheric conditions
         (i) Blend
      (7) Harmful chemicals and gum

Section 9: Electrical System

I. Purpose of Electrical System
A. Cranks Engine for Starting
B. Helps Create High-Voltage Surge for Ignition
C. Provides Electrical Current for Electrically Operated Devices

II. Components of Electrical System
A. Storage Battery
B. Cranking Motor
C. Generator/Alternator
D. Regulators
E. Ignition Distributor (Timer)
F. Magneto
G. Coil
H. Spark Plugs
I. Wiring
J. Switches
K. Accessory Units

14690

III. Fundamentals of Electricity
- A. Characteristics
  1. Atoms
     a. Electrons: negative (–)
     b. Protons: positive (+)
  2. Attraction of opposite charges
  3. Repulsion of like charges
  4. Accumulation of electrons: electric charge
  5. Accumulation of electrons by generators and batteries
- B. Principles of Electric Current
- C. Conductors
  1. Example: copper
  2. Free movement of electrons
- D. Insulators
  1. Example: rubber
  2. Few free electrons
  3. Prevention of loss of electrons from conductors
- E. Electrical Terms
  1. Voltage
     a. Electric pressure
     b. Pressure measured in volts
  2. Amperage
     a. Current flow
     b. Flow measured in amperes
  3. Resistance
     a. Resistance to electrical pressure
     b. Resistance measured in ohms
- F. Ohm's Law
- G. Circuits
  1. Series
     a. Current flow same in all parts of circuit
     b. Total resistance equal to sum of individual resistances
     c. Voltage equal to sum of potential differences across each of individual resistances
  2. Parallel
     a. Voltage same across all resistances
     b. Total current equal to sum of currents through branches
     c. Total resistance equal to voltage across resistances divided by total circuit current
  3. Series-parallel
     a. Certain components in series
     b. Certain components in parallel
- H. Magnetism
  1. Magnets: characteristics
  2. Lines of force
     a. Stretch between magnetic poles
     b. Tend to be parallel (do not cross)
- I. Electromagnetism
  1. Lines of force produced by current flow
  2. Electromagnets: combined magnetic field
  3. Permeability
     a. Iron core in coil
     b. Increased magnetic field

IV. Storage Battery
- A. Purpose
- B. Construction
  1. Container
  2. Plates
     a. Positive: lead peroxide
     b. Negative: sponge lead
  3. Separators
  4. Post straps
  5. Terminal posts
  6. Cell covers
  7. Cell connectors (internal and external)
  8. Vent plugs
  9. Sealing compound
- C. Principles of Chemical Activity
- D. Battery Ratings
  1. Definition
     a. Total area
     b. Volume of active plate material
     c. Amount of electrolyte
     d. Strength of electrolyte
  2. Methods of rating
     a. Ampere-hour capacity
     b. Cold rating

V. Cranking Motor
- A. Purpose
- B. Principles of Motor Operation
  1. Magnetic field around conductor
  2. Conductor in magnetic field
  3. Lines of force action
  4. Current flow
- C. Construction of Cranking Motor
  1. Basic elements
     a. U-shaped conductor
     b. Contacts
     c. Brushes
     d. Magnets
     e. Battery
  2. Components of cranking motor
     a. Armature
     b. Field-frame assembly
     c. Commutator end-head assembly
     d. Brushes
     e. Drive housing
     f. Drive mechanism
     g. Solenoid assembly
     h. Shift-lever assembly
- D. Cranking-Motor Drives
  1. Purpose
  2. Types
     a. Overrunning clutch
     b. Inertia
        (1) Bendix drive
        (2) Dyer drive
        (3) Folo-thru drive
     c. Principles of operation

14691

E. Cranking-Motor Controls
  1. Purpose
  2. Manual operation
  3. Automatic control: solenoid
  4. Methods of operation
F. Simple Wiring Diagram

VI. Direct-Current Generator
A. Purpose
B. Principles of Generator Operation
  1. Conductor moving through magnetic field
  2. Current flow
  3. Magnetic lines of force
  4. Rate of cutting lines of force
C. Construction of Generator
  1. U-shaped conductor
  2. Contacts
  3. Brushes
  4. Field coils
  5. Drive unit
D. Components of Generator
  1. Frame assembly
    a. Frame
    b. Field coil
    c. Pole shoes
    d. Terminals
  2. Armature
  3. Commutator end frame
  4. Brushes
  5. Drive end frame
  6. Fan
  7. Pulley
E. Output control
F. Wiring diagram

VII. Generator Regulators (Conventional and Transistorized)
A. Purpose
B. Cutout Relay (Circuit Breaker)
  1. Purpose
  2. Construction
    a. Two windings
      (1) Current
      (2) Voltage
    b. Core
    c. Armature
    d. Contacts
    e. Spring
  3. Operation
    a. Voltage buildup
    b. Magnetic field produced
    c. Spring tension overcome
    d. Armature closes
    e. Generator current flowing
      (1) Current flows to battery from generator
      (2) Magnetic field buildup
      (3) Points held closed by current
    f. Generator current flowing
      (1) Current flows from battery to generator
      (2) Magnetic fields reversal-weakened
      (3) Contact points separate
      (4) Circuit opens
C. Voltage Regulator
  1. Purpose
    a. Prevents excessive voltage
    b. Maintains constant voltage
  2. Operation
D. Current Regulator
  1. Purpose
    a. Regulates current to battery
    b. Protects battery
  2. Operation

VIII. Alternating-Current Generator System (Alternator)
A. Wiring Diagram of Alternator Circuit
B. Function of Alternating-Current Generator (Alternator)
C. Construction and Description of Parts
D. Principles of Alternator Operation

IX. Ignition System (Conventional and Transistorized)
A. Purpose
B. Components
  1. Battery
  2. Switch
  3. Resistor
  4. Coil
  5. Distributor
  6. Spark plugs
  7. Wiring
  8. Switch
  9. Timer
C. Distributor
  1. Purpose
    a. Closes and opens circuit between battery and coil
    b. Distributes high-voltage surge to spark plugs
  2. Location
  3. Construction
    a. Housing
    b. Drive shaft
      (1) Breaker cam
      (2) Advance mechanism
    c. Breaker plate
    d. Contact points
    e. Rotor
    f. Cap
  4. Operation
  5. Spark advance mechanisms
    a. Purpose
    b. Types and operation
      (1) Centrifugal
      (2) Vacuum
      (3) Combination
      (4) Full vacuum
D. Spark Plugs
  1. Purpose
  2. Location

14692

3. Construction
   a. Shell
   b. Insulator
   c. Electrodes
      (1) Center
      (2) Ground
   d. Terminal
   e. Sealing methods
   f. Threads
4. Heat ranges
   a. Heat path
   b. Hot
   c. Cold
5. Spark gap
6. Operation

E. Ignition Coil
1. Purpose
2. Location
3. Construction
   a. Case
   b. Coils (wire)
      (1) Primary
      (2) Secondary
   c. Iron core
   d. Insulating materials
   e. Terminals
      (1) Primary
      (2) Secondary
4. Operation
   a. Creating magnetic field
   b. Collapsing magnetic field: primary
   c. Collapsing magnetic field: secondary
   d. Capacitor (condenser) effect

F. Ignition Switch
1. Purpose
2. Operation

G. Wiring Diagram
1. Primary circuit
2. Secondary circuit

H. Ignition Timing Marks
1. Purpose
2. Location

X. Electrical Circuits
A. Horn
B. Lights (Internal)
C. Running Lights
1. Headlights
2. Taillights
3. Stop lights
4. Back-up lights

D. Directional Signals
E. Accessories

XI. Relays
A. Purpose
B. Uses
1. Lighting
2. Horn

Section 10: Engine-Trouble Diagnosis

I. Engine Failure
A. Compression Loss
B. Failure of Engine to Turn Over
C. Ignition Troubles
D. Carburetion Troubles

II. Compression Loss
A. Causes
1. Cylinder bore wear
2. Improper valve timing
3. Improper valve seating
4. Cylinder-head gasket
5. Cracks

B. Trouble Checklist
1. Crank engine; diagnose compression noises
2. Make compression test
3. Observe valve action
4. Check valve adjustment

III. Failure of Engine to Turn Over
A. Causes
1. Piston and ring fit
2. Bearing clearances
3. Valve action
4. Lubrication system
5. Cooling system
6. Starting system

B. Trouble Checklist
1. Check lubricating oil
2. Check water
3. Turn crankshaft by hand, if possible
4. Observe valve action
5. Diagnose abnormal knocks and noises

IV. Carburetion Troubles
A. Causes
1. Carburetor circuits
   a. Float
   b. Idle
   c. Part throttle
   d. High speed
   e. Accelerator pump
   f. Choke
2. Fuel pump
3. Fuel tank
4. Fuel lines
5. Manifold and exhaust system

B. Trouble Checklist
1. Check fuel level in tank
2. Check accelerator action
3. Remove carburetor fuel line; crank engine
4. Check fuel pump
5. Test fuel lines
6. Check air cleaner

V. Ignition Troubles
A. Causes
1. Primary system
   a. Battery

14693 1963

PATTERN ADJUSTMENT FOR NARROW SHOULDERS

Diagram shows wrinkles and distortion of grain line on ill fitting garment caused by narrow shoulders.

Diagram shows bodice back and front pattern pieces altered by taking a tuck in pattern at shoulder to create new shoulder and armscye line.

Fig. 1
1968

b. Switch
c. Primary winding
d. Connections
e. Voltage-dropping resistor
f. Coil primary-winding
g. Distributor points
h. Capacitor (condenser)
i. Ground return to battery

2. Secondary system
a. Coil secondary-winding
b. Distributor rotor
c. Distributor cap
(1) Broken
(2) Moisture
d. High-tension wiring
e. Spark plugs
f. Ground return through part of primary system

B. Trouble Checklist (Use of Jumper Wire and Voltmeter)
1. Remove coil wire from distributor
a. Crank engine
b. Check spark
2. Check battery side of coil
a. Check switch
b. Inspect wiring and battery connections
3. Check distributor side of coil
a. Check points
b. Inspect wiring and connections
c. Check capacitor (condenser)
4. Check ignition timing

Section 11: Clutches

I. Purpose of Clutch
A. Used with Standard Transmissions
B. Couples or Uncouples Engine and Transmission
1. Coupled position (normal running)
a. Power to transmission
b. In gear: power to rear wheels
2. Uncoupled position
a. Allows gears to be shifted easily
b. Allows engine to run with transmission in gear
C. Provides Gradual but Positive Application of Engine Power to Power Train
1. Minimizes shock
2. Provides comfortable starts

II. Principles of Operation
A. Frictional Contact Made Between Two Smooth Metallic Driving Surfaces and Facings Riveted to Driven Disk
1. Flywheel and pressure plate: driving surfaces
2. Friction disk: driven plate
B. Flywheel, Pressure Plate, and Friction Disk Held Together by Pressure Springs
C. Hub of Friction Disk Splined to Clutch Shaft
D. Clutch Uncoupled by Release of Spring Pressure on Pressure Plate by Operation of Clutch Pedal
E. Flywheel and Pressure Plate Permitted to Turn Independently of Friction Disk

III. Types of Clutches
A. All Similar in Construction and Operation
1. Expanding clutches
2. Contracting clutches
3. Cone clutch
4. Dry-disk clutches
a. Coil pressure-spring type
b. Diaphragm-spring type
c. Crown pressure-spring type
5. Multiple dry-disk clutches
6. Oil-bath disk clutches
a. Multiple disk
b. Single disk
B. Most Commonly Used Clutch: Single Dry-Disk

IV. Friction Disk
A. Hub Assembly
1. Splined hub
a. Splined to clutch shaft
b. Allows movement lengthwise
c. Forces hub to turn with clutch shaft
d. Must fit snugly yet without drag or bind
2. Torsional springs
a. Placed between drive washers
b. Absorbs torsional vibration from engine
c. Absorbs some engaging shock
3. Hub flange
4. Drive washers
5. Molded friction washer
a. Located between hub flange and drive washer
b. Prevents oscillation between hub flange and drive washer
6. Movement of hub flange limited by stop pin
B. Disk Assembly
1. Friction rings or clutch facings
a. Made of frictional material
(1) Asbestos main part of composition
(2) Heat-resistant materials
b. Provides proper amount of slipping when starting
c. Provides positive nonslipping drive when engaged
d. Usually riveted to cushioning springs
2. Cushioning springs
a. Provide cushioning effect as clutch is engaged
b. Produce smoother engagement
c. Consist of waved cushion springs
d. Waves compress when engaged

V. Pressure-Plate Assembly
A. Pressure Plate and Flywheel
1. Both driving surfaces
2. Surfaces smooth, parallel
3. Friction disk between driving surfaces
B. Clutch Cover
1. Bolted to flywheel
a. Becomes part of flywheel

14694

b. Rotates with flywheel
c. All parts of pressure-plate assembly attached to clutch cover
2. Houses pressure spring arrangement
3. Houses clutch release mechanism

C. Pressure Springs
1. Coil
a. Contains three to nine springs
b. Spring loads friction disk between pressure plate and flywheel when coupled
c. Clutch released by compression of springs
2. Diaphragm (tapering-finger type)
a. Provides spring pressure to pressure plate
b. Acts as release levers
c. Reacts similarly to bottom of oil can when depressed
(1) Tapered fingers depressed
(2) Diaphragm pivots on pivot ring
(3) Outer edge raises
(4) Works against retracting spring to pressure plate
(5) Pressure plate pulled away from friction disk
d. Clutch engaged by built-in spring tension of diaphragm
3. Crown
a. Variation of diaphragm type
b. Diaphragm formed of single corrugated plate of spring metal
c. Action (same as in V.C.2.c.)

D. Release Levers
1. Purpose: to disengage clutch by relieving spring pressure to pressure plate
a. Coil-spring type
(1) Usually three levers
(2) Adjustable
(a) Adjustment screws
(b) Uniform pressure
b. Diaphragm-spring type
(1) Tapered fingers
(2) Nonadjustable
c. Crown-spring type
(1) Corrugated edge release
(2) Nonadjustable
2. Release levers depressed by throw-out bearing

VI. Throw-Out Mechanism
A. Clutch-Shaft Bearing Retainer and Sleeve
1. Front transmission bearing retained
2. Clutch shaft covered by sleeve
B. Throw-Out Collar
1. Slides on clutch shaft sleeve
2. Holds throw-out bearing
C. Clutch-Release Fork
1. Pivots on flywheel housing: ball stud
2. Moves throw-out bearing and collar forward
D. Throw-Out Bearing
1. Sealed ball bearing
2. Mounted on throw-out collar
3. Moved forward against release levers
4. Turns with the release levers
5. Depresses release levers, disengaging clutch

VII. Clutch Pedal and Linkage
A. Effects of Depressing Clutch Pedal
1. Clutch pedal arm depressed
2. Rotation of clutch pedal shaft
3. Adjusting link pushed or pulled
4. Rotation of cross shaft (if included)
5. Forward movement of throw-out fork
a. Forward movement of throw-out bearing
b. Release levers depressed
c. Pressure plate pulled away from friction disk
B. Effects of Releasing Clutch Pedal
1. Return of clutch pedal arm (assisted by return spring)
2. Clutch fork pulled back by linkage
3. Throw-out bearing pulled away from release levers
4. Return of release levers
5. Pressure plate, friction disk, and flywheel compressed by pressure springs
C. Hydraulically Clutch Operated

VIII. Clutch Shaft Support
A. Crankshaft End of Clutch Shaft Supported in End of Crankshaft or Center of Flywheel by Bushing, Roller, or Ball Bearing
B. Shaft to Be in Perfect Alignment (Will not "Whip")

IX. Semicentrifugal Clutch
A. Clutch Similar in Construction to Coil-Pressure-Spring Clutch
B. Weights Placed on Outer Ends of Release Levers
C. Added Pressure on Pressure Plate Exerted by Release Levers Because of Increased Speed
D. Centrifugal Action When Clutch Begins to Revolve

X. Clutch Trouble Diagnosis
A. Slipping
B. Chattering or Grabbing
C. Spinning or Dragging
D. Noises (When Engaged, Disengaged)
E. Pedal Pulsation
F. Friction-Disk Facing Wear

Section 12: Standard Transmissions and Overdrives

I. Purpose of Transmission
A. Provides Means of Varying Gear Ratios Between Engine and Rear Wheels
1. Ratios between engine and rear wheels (approximately)
a. Low gear ..... 12 to 1
b. Second gear ..... 8 to 1
c. High gear ..... 4 to 1
d. Reverse gear ..... 12 to 1
2. Ratios between clutch shaft and transmission main shaft
a. Low gear ..... 3 to 1

14695

b. Second gear ..... 2 to 1
c. High gear ..... 1 to 1
d. Reverse gear ..... 3 to 1

B. Provides Reverse Gear for Backing Car

II. Transmission Gears
A. Relative Speed of Rotation (Gear Ratio)
1. Speed determined by number of teeth
a. Same number of teeth
(1) Turn at same speed
(2) Gear ratio: 1 to 1
b. Different number of teeth
(1) Smaller gear turns faster
(2) Large gear 24, smaller gear 12; gear ratio: 2 to 1
2. Number of teeth of driven gear divided by number of teeth of driving gear to determine ratio
B. Direction of Rotation
1. Turn in opposite directions (when two gears mesh)
2. Idler gears
a. Change direction of rotation
b. Do not change gear ratio between driving gear and driven gear
C. Types of Gears
1. Spur gear
2. Helical gear
3. Bevel gear
4. Skew-bevel gear
5. Worm gear
6. Rack gear
7. Pinion gear
8. Planetary gears
a. Internal or ring
b. Planetary
c. Sun
d. Spider or planet carrier

III. Torque (Transmission)
A. Change of Torque According to Gear Ratio
B. Torque in Any Turning Shaft or Gear
1. Torque applied to crankshaft
2. Torque supplied by crankshaft to gears in transmission so that gears turn
3. Torque carried through power train to rear wheels, causing rear wheels to turn
C. Torque on Gears Measured as Straight-Line Force at Distance from Center of Gears
D. Torque Ratio Opposite to Gear Ratio
E. Torque Increase Caused by Reduction of Gear Speed

IV. Basic Standard Transmission
A. Gears
1. Clutch or main drive gear
2. Cluster gear or countershaft gears
a. Countershaft drive gear
b. Countershaft second gear
c. Countershaft low gear
d. Countershaft reverse gear
3. Main-shaft low and reverse sliding gear
4. Main-shaft second and high sliding gear
5. Reverse idler gear
B. Shafts
1. Clutch or pilot shaft
2. Countershaft
3. Transmission main shaft
4. Reverse idler gear shaft
C. Thrust Washers
1. Countershaft
2. Main shaft
3. Reverse idler shaft
D. Bearings
1. Clutch gear bearing
2. Main-shaft rear bearing
3. Front pilot bearing
4. Countershaft bearings
5. Reverse idler bearing
E. Bearing Retainers
1. Clutch gear bearing retainer and throw-out bearing sleeve
2. Main-shaft bearing retainer
F. Transmission Case
G. Shifting Mechanism
1. Shifting forks
2. Shifting levers (side mount)
3. Cover

V. Operation of Basic Standard Transmission
A. Neutral
B. Low Gear
C. Second Gear
D. High Gear
E. Reverse Gear

VI. Gearshift Lever (Transmission)
A. H-Pattern
B. Two Separate Motions
1. Selection of gear assembly
2. Movement of gear assembly

VII. Transmission Synchronizing Device (Synchromesh)
A. Gears About to Mesh Made to Rotate at Same Speed
1. Mesh without clashing of gears
2. Easier shifting
3. Less wear on transmission parts
B. Synchromesh Types
1. Cone-clutch type (Ford)
2. Pin type (Dodge)

VIII. Constant-Mesh Transmission
A. Main-Shaft and Countershaft Second Gears Always in Mesh
B. Constant Mesh Used in Conjunction with Synchromesh
C. Principles of Operation

IX. Selector and Shifter (Transmission)
A. Types of Selector and Shifter Devices
B. Steering-Column Gearshift Mechanism
C. Floor-Shift Mechanism

14696

X. Transaxle Units: Similar in construction and operation to other standard transmissions

XI. Purpose of Overdrive
- A. Establish More Favorable Gear Ratio
- B. Reduce Engine Speed at High Car Speed
- C. Provide More Economical Operation
- D. Lessen Engine and Accessory Wear Per Car Mile
- E. Drop Engine Speed About 30 Percent

XII. Method of Operation (Overdrive)
- A. Automatic
  1. Operation automatic at about 30 miles per hour
  2. Selective
     - a. Direct drive
     - b. Into overdrive: foot to be raised from accelerator
     - c. Out of overdrive
       - (1) Accelerator to be depressed "wide open"
       - (2) Throttle switch actuated
- B. Two Separate Controls
  1. Centrifugal device (governor)
  2. Electrical control (solenoid)

XIII. Freewheeling Mechanism (Overdrive)
- A. Coupling Between Two Shafts in Line with Each Other (Overrunning Clutch)
  1. Inner shell
  2. Outer shell
  3. Rollers between
- B. Solid Drive When Power Delivered to Input Shaft
- C. Output Shaft Overrun Because of Slowdown of Input Shaft
  1. Uncoupling of clutch
  2. Free turning of output shaft
  3. Input shaft on transmission
  4. Output shaft on propeller shaft
- D. Mechanical Principles of Operation

XIV. Planetary-Gear System (Overdrive)
- A. Components
  1. Outer ring gear (internal gears)
  2. Three planet pinions
  3. Planet-pinion cage
  4. Planet-pinion shafts
  5. Sun gear
  6. Sun-gear shaft
  7. Ring-gear shaft
- B. Principles of Operation
  1. Speed increase (sun gear stationary)
     - a. Planet-pinion cage turning
     - b. Sun gear stationary
     - c. Planet-pinion shafts carried around with cage
     - d. Planet pinions
       - (1) Rotate on shafts
       - (2) "Walk around" stationary sun gear
       - (3) Cause ring gear to rotate
  2. Speed increase (ring gear stationary)
     - a. Ring gear stationary
     - b. Planet-pinion cage turning
     - c. Sun gear rotating faster than cage
     - d. Driven member turning faster than driving member
  3. Speed reduction (ring gear turning)
     - a. Ring gear turning
     - b. Sun gear stationary
     - c. Planet-pinion cage turning slower than ring gear
     - d. Driven member turning slower than driving member
  4. Speed reduction (ring gear stationary)
     - a. Ring gear stationary
     - b. Sun gear turning
     - c. Planet pinions
       - (1) Turn on shafts
       - (2) "Walk around" ring gear
       - (3) Planet-pinion cage rotates
     - d. Cage rotating slower than sun gear
     - e. Driven member turning slower than driving member
  5. Reverse (planet-pinion cage stationary)
     - a. Planet-pinion cage stationary
     - b. Ring gear turning
     - c. Planet pinion
       - (1) Acts as reverse idlers
       - (2) Causes sun gear to turn in reverse direction to ring gear
     - d. Sun gear turning faster than ring gear
  6. Reverse (planet-pinion cage stationary)
     - a. Planet-pinion cage stationary
     - b. Sun gear turning
     - c. Ring gear turning opposite to and slower than sun gear
  7. Direct drive
     - a. Any two members locked together: then entire planetary-gear system locked, and input and output shafts turn at same speeds
     - b. No member held stationary and no two members locked together: system will not transmit power at all
- C. Application to Overdrive
  1. Ring gear attached to output shaft
  2. Planet-pinion cage splined to transmission main shaft
  3. Sun gear
     - a. May be permitted to turn free
     - b. May be locked in stationary position
       - (1) Ring gear (output shaft) forced to turn faster than transmission main shaft
       - (2) Transmission main shaft "overdriven" by output shaft

XV. Nomenclature (Overdrive)
- A. Clutch Cam
- B. Transmission Main Shaft
- C. Sun Gear
- D. Pinion-Cage Assembly
- E. Ring Gear
- F. Pinions

814697

G. Output Shaft
H. Output-Shaft Bearing
I. Clutch-Cam Rollers
J. Control Shaft and Lever
K. Shift Fork
L. Solenoid Assembly
M. Control Rod
N. Sun-Gear Pawl
O. Blocker Ring
P. Sun-Gear Plate
Q. Governor

XVI. Overdrive Operation
A. Going into Overdrive
1. Car speed approaching 18 to 20 miles per hour
2. Sun-gear pawl retracted
3. Governor closing electrical contact
4. Solenoid energized
a. Spring loading solenoid pawl
b. Pawl held away by blocker ring
5. Accelerator pedal momentarily released by driver
a. Engine speed dropping
b. Freewheeling mechanism going into action
c. Output shaft overrunning transmission main shaft
(1) Sun gear slowing and reversing direction
(2) Moving blocker ring
(3) Pawl moving inward
(a) Registers with notch on sun-gear control plate
(b) Locks control plate: stationary
(c) Locks sun gear: stationary
6. Driver accelerating and engine speed increasing: car going into overdrive (See XIV.B.1.)
B. Coming Out of Overdrive: Accelerator Pedal Depressed
1. Operates kick-down switch
2. Produces two actions
a. Opens solenoid circuit
(1) Attempts to withdraw pawl
(2) Considerable pressure against pawl
b. Grounds out ignition circuit
(1) Prevents engine from delivering power
(2) Relieves driving thrust on sun gear
(3) Pawl pulled back by solenoid
(4) Ignition circuit reopened by solenoid
C. Locking Out of Overdrive: Control Knob Pulled
1. Actuates control rod
2. Moves shift fork
a. Sun gear meshing with ring gear
b. Sun gear and ring gear locking
3. Locks sun-gear pawl
D. Reversing
1. Overdrive to be locked out (shaft mechanism reversed by transmission)
2. Overdrive control rod moved to lockout position when reverse shift is made

XVII. Overdrive Electrical Components
A. Battery
B. Ignition Switch
C. Relay
D. Kick-down Switch
E. Governor Switch
F. Ignition Coil and Distributor
G. Solenoid
1. Ground-out contact
2. Pull-in and hold-in winding
H. Wiring

Section 13: Automatic Transmissions

I. Main Sections of Automatic Transmission
A. Clutch Coupling or Torque Converter
B. Planetary Gear Box

II. Fluid Coupling (Torus)
A. Fluid Coupling Theory
1. Two fans facing each other
2. Oil coupling driving and driven torus (straight vanes in both torus units)
B. Engine Flywheel to Torus Cover Drive
C. Torus Cover to Driving Torus
D. Driven Torus and Input Shaft
E. Acts as Clutch

III. Torque Converter
A. Torque Converter Theory
1. Two fans facing each other
2. Stator redirecting oil at different angle to turbine
3. Torque multiplied
B. Engine Flywheel to Torque Converter Cover
C. Pump (Impeller) to Stator to Turbine
D. Turbine to Stator, Where Oil Is Returned to Pump
1. Turbine driving input shaft
2. Spiral vanes on turbine
E. Three Jobs of Stator
1. As stationary member for oil to push against
2. Redirects oil to pump
3. Overruns (like a bicycle coaster brake) when car reaches cruising speed
F. Torque Conversion Ended at Cruising Speed, with Coupling Taking Place

IV. Planetary Gears
(Review Section 12 of this outline.)

V. Automatic Transmission Operation
A. Oil Pump (to Supply Pressure)
B. Pressure Regulator Maintaining Constant Pressure
C. Shift Valve Directing Oil to Band-Servo or Clutch-Piston Action
D. Manual Valve Turning Oil Pressure On or Off
E. Governor
1. Operated by centrifugal force to make shifts occur automatically
2. Attached to transmission output shaft and thus sensitive to car speed

CC04 4698

F. Throttle Valve
   1. Operated by accelerator pedal position to time shifts
   2. Works in opposition to governor pressure and thus sensitive to engine speed

VI. Automatic Transmission Maintenance
   A. Checking Oil Level
   B. Changing Oil

Section 14: Drive Lines

I. Purpose of Drive-Line Assembly
   A. Transfers Power from Transmission to Differential
      1. Change in angle
      2. Change in length
   B. Absorbs Rear-End Torque

II. Components of Drive Line
   A. Universal Joints
   B. Slip Joints
   C. Propeller Shaft
   D. Torque Tube
   E. Universal Ball Joint
   F. Supporting Members

III. Universal Joints
   A. Purpose
   B. Types
      1. Cross and Yoke
         a. Yoke
         b. Spider
         c. Trunnions
         d. Needle bearings
      2. Ball and trunnion
         a. Propeller shaft
         b. Pin
         c. Body
         d. Ball
         e. Needle bearings
         f. Centering button
         g. Grease cover
      3. Constant velocity
         a. Reasons for
         b. Construction
            (1) Body
            (2) Balls
   C. Operation
      1. Cross and yoke
      2. Ball and Trunnion
      3. Constant velocity
         a. Bendix
         b. Double cross and yoke

IV. Slip Joints
   A. Purpose
   B. Types
      1. Splines
      2. Built-in (ball and trunnion)

V. Types of Drive
   A. Torque-Tube Drive
      1. Construction
         a. Propeller shaft enclosed
         b. Universal joints
            (1) Type used
            (2) Number
         c. Universal ball joint
         d. Slip joints
         e. Support members
      2. Rear-end torque absorption
      3. Push delivered to front section of chassis
   B. Hotchkiss Drive
      1. Construction
         a. Propeller shaft exposed
         b. Universal joints
            (1) Type used
            (2) Number
         c. Slip joints
         d. Support members
      2. Rear-end torque absorption
      3. Push delivered to rear section of chassis
   C. Curved Flexible Shaft
      1. Construction
         a. Three-inch bow
         b. Ball-bearing pillow blocks
         c. No slip joints
         d. No universal joints
      2. Rear-end torque absorption
      3. Push delivered to rear section of chassis

Section 15: Rear Axles and Differentials

I. Purpose of Differential
   A. Transmits Rotary Power Through Right Angle
   B. Allows Different Rear-Axle Speed
      1. Prevents skidding in turns
      2. Improves steering control

II. Types of Differentials
   A. Conventional
   B. Nonslip (Limited Slip)
   C. Transaxle

III. Differential Components (Major)
   A. Differential-Side Gears
   B. Differential-Pinion Gears
   C. Differential-Pinion Shaft
   D. Differential Case
   E. Ring Gear
   F. Drive Pinion
   G. Drive-Pinion Carrier and Caps
   H. Differential-Bearing Adjusters
   I. Differential Bearing (Cone and Rollers)
   J. Axles (Axle Drive Shafts)

IV. Differential Power Flow
   A. Drive Pinion Driven by Propeller Shaft
   B. Drive Pinion Meshed with Ring Gear
   C. Ring Gear Bolted to Differential Case, Causing Case to Turn (Rotate)
   D. Differential-Pinion Shaft Mounted in Case

SECRET 14699

E. Differential-Pinion Gears Mounted on Shaft
F. Differential-Pinion Gears Meshed with Side Gears
G. Differential-Side Gears Splined to Axles

V. Differential Gear Action
A. Straight Ahead
1. Differential-pinion gears not rotating
2. Equal pressure exerted on side gears
3. Both wheels turning at same speed
B. Turning
1. Two pinion gears rotating on shaft
2. More turning movement exerted to outer side gear with same amount of torque
3. Outside wheel turning more rapidly

VI. Nonslip Differential
A. Similar in Construction to Conventional Type
B. Incorporates Two Sets of Clutch Plates (or Cones) Between Side Gears and Case
C. More Power Instead of Less Applied to Drive Wheel Hard to Turn

VII. Differential Gearing
A. Manner of Gear Reduction
B. Variance of Ratios According to Make and Application
1. Passenger cars (3.36:1 to 5:1)
2. Heavy- duty applications (9:1 by double reduction)
C. Calculation of Gear Ratio
D. Types of Gears
1. Spur (obsolete)
2. Spiral bevel (nearly obsolete)
a. More gear tooth contact
b. Even wear
c. Quieter operation
3. Hypoid
a. Similar to spiral bevel
b. Drive pinion lowered
c. Wiping action
d. Needs special lubricant
E. Nomenclature of Gears
1. Toe
2. Heel
3. Flank
4. Face
5. Pitch line
F. Gear Measurements
1. Clearance
2. Backlash

VIII. Rear Axles
A. Purpose
B. Types
1. Dead
2. Live
a. Semifloating
b. Three-quarter floating
c. Full-floating

IX. Differential Trouble Diagnosis
A. Noises Mistaken for Gear-Axle Noises
1. Road noise
2. Tire noise
3. Front-wheel bearing noises
4. Engine and transmission noises
B. Rear-Axle Bearing
1. Wheel bearing
2. Side gear and pinion
3. Pinion bearing
4. Ring and pinion noise
a. Drive
b. Coast
c. Float
d. Drive, coast, and float
5. Nonslip differential chatter

Section 16: Suspension Systems

I. Purpose
A. Support Weight of Front End of Car
B. Permit Steering of Car: Provide Safer Steering Control
C. Absorb Shock Through Springs
D. Provide Ride Control

II. Types of Front Suspension
A. Rigid Axle
B. Independent Front Suspension

III. Rigid Axle
A. Applications
1. Heavy-duty trucks and buses
2. Industrial vehicles
3. Early model autos
B. Construction
1. Beam
2. Steering knuckle
3. Kingpin
4. Leaf spring
C. Characteristics
1. Both front wheels affected by any surface change
2. Gyroscopic effect of tilted wheels

IV. Independent Front Suspension
A. Construction
1. Upper control arm
2. Lower control arm
3. Steering-knuckle support
4. Steering knuckle
5. Spring
6. Stabilizer shaft or sway bar
7. Shock absorber
B. Operating Characteristics
1. Wheels completely independent of each other
2. Better ride control
3. Smoother ride
C. Variations in Design of Independent Front Suspension
1. Coil spring
2. Transverse leaf spring

TOTAL 14700

3. Torsion-bar spring
4. Ball-joint front suspension
   a. Replaces steering knuckle and support
   b. Uses spherical joints
   c. Uses fewer moving parts

V. Springs
A. Purpose
B. Operating Characteristics
   1. Rate
   2. Frequency
C. Types
   1. Leaf
   2. Coil
   3. Torsion bar
   4. Air suspension
D. Leaf Spring
   1. Common types
      a. Semielliptic
      b. Quarter elliptic
   2. Installation
      a. Transverse
      b. Longitudinal
   3. Construction
      a. One or more leaves
      b. Master leaf
      c. Spring seat
      d. Center bolt
      e. U-bolt
      f. Rebound clips
      g. Spring eye
      h. Spring hanger
      i. Spring shackle
      j. Bushings
E. Coil Spring
   1. Operating characteristics
      a. Free of friction
      b. Requires efficient shock absorber
   2. Installation
      a. Requires linkage to support vehicle thrust
      b. Used primarily in front suspension
F. Torsion-Bar Spring
   1. Operation
      a. Twisting action
      b. Free of friction
      c. Provision for adjustment
      d. Lightweight
   2. Construction
      a. Spring-steel round shaft
      b. Linkage
      c. Adjustable anchor
G. Air Suspension
   1. Operation
   2. Construction
      a. Air-bag or air-spring assembly
      b. Air compressor
      c. Leveling valves

VI. Shock Absorbers
A. Purpose
   1. Dampen spring oscillations
   2. Keep wheels on pavement
   3. Provide better control
   4. Provide smooth ride
B. Types
   1. Hydraulic
      a. Direct-acting
      b. Opposed-cylinder
      c. Parallel-cylinder
      d. Rotating-vane
   2. Friction
C. Theory of Operation
   1. Hydraulic principles
   2. Forcing liquid through orifice
D. Testing

VII. Front-End Geometry
A. Definition
B. Purpose
   1. Provide steering ease
   2. Provide steering stability
   3. Provide maximum tire life
   4. Provide ride quality
C. Classifications
   1. Camber
      a. Positive
      b. Negative
   2. Kingpin inclination
   3. Caster
      a. Positive
      b. Negative
   4. Toe-in
   5. Include angles
   6. Toe-out on turns
D. Methods of Adjustment

Section 17: Steering Systems

I. Purpose of Steering System
A. Guide Car
B. Provide Easy Steering

II. Early Steering Systems
A. Tiller
B. Fifth-Wheel Steering

III. Ackerman Steering System
A. Front Wheels Supported on Pivots
B. Front Wheels Linked to Steering Wheel by Gears and Levers

IV. Classification of Steering Systems
A. Manual
B. Power
   1. Integral or hydraulic
   2. Linkage or mechanical

V. Manual Steering Gears
A. Recirculating Ball and Nut

14701 14700

B. Worm and Roller
C. Cam and Lever

VI. Steering Linkage
A. Steering Wheel
B. Steering Shaft
C. Steering Gear
D. Pitman Arm
E. Drag Link or Steering Connecting Rod
F. Tie Rod(s)
G. Relay Rod
H. Steering Arms
I. Steering Knuckles
1. Knuckle support
2. Kingpin
J. Ball Joints
K. Spindle
L. Wheel Bearings

VII. Power-Steering Operation
A. Hydraulic
1. Power-steering pumps
a. Construction
b. Operation
c. Location
2. Power-operating mechanism
a. Valve operation
b. Power cylinders
B. Mechanical
1. Construction
2. Operation
3. Location

Section 18: Tires and Tubes

I. Purpose of Tires
A. Provides Cushion
1. Absorbs shock
2. Tire flexes
B. Provides Frictional Contact
1. Minimizes skidding on turns
2. Provides for quick stops

II. Casing Construction
A. Plies (Variable Number)
B. Bead
C. Sidewall
1. Black
2. White
3. Colored
D. Curb Bead
E. Shoulder
F. Tread
1. Design
2. Purpose
a. Provide traction
b. Reduce surface area
c. Cool tire

III. Types of Tires
A. Solid
B. Pneumatic
1. Tube
2. Tubeless
3. Puncture-sealing
C. Materials
1. Natural rubber
2. Synthetic rubber

IV. Tire Sizes
A. Rim Size
B. Thickness at Sidewalls
1. Inflated
2. No load

V. Inner Tubes
A. Materials
1. Rubber
2. Synthetic
B. Air Valve
1. Stem
2. Core
3. Cap
C. Special Tubes
1. Puncture-sealing
2. Safety tube

VI. Tire Inflation
A. Proper Inflation
B. Low Pressure
1. Hard steering
2. Front-wheel shimmy
3. Steering kickback
4. Side of tread worn
5. Excessive flexing
a. Heat
b. Ply separation
6. Rim bruises
C. Excessive Pressure
1. Center of tread worn
2. Hard ride
3. Fabric rupture
D. Uneven Pressure (Pulls to Side)

VII. Tire Rotation
A. Purpose
B. Procedure

VIII. Causes of Tire Wear
A. Excessive Speed
B. Improper Inflation
C. Improper Front-Wheel Alignment
1. Excessive camber
2. Excessive toe-in or toe-out
D. Improperly Adjusted Brakes
E. Unbalanced Wheels
F. Incorrect Steering-Linkage Adjustment

IX. Recapping and Regrooving Tires

14703
14702

Section 19: Wheel Balance

I. Purpose of Wheel Balance
  A. Provide Ease of Steering
  B. Provide Comfortable Ride
  C. Provide Maximum Tire Mileage

II. Problems of Balancing Wheels
  A. Centrifugal Force
  B. Making Wheel Run True (Must Be Round)
  C. Flexing of Tire on Wheel
  D. Wheel Tramp (Bounce and Wobble)

III. Types of Wheel Imbalance (Out of Balance)
  A. Static
    1. Lies in plane of wheel rotation
    2. Causes front and rear wheels to bounce
  B. Dynamic
    1. Lies in zone on either or both sides of plane of rotation
    2. Causes front wheels to wobble as well as bounce

IV. Types of Balance
  A. Static
    1. Balanced wheel assembly, when on spindle, remains in fixed position regardless of how placed on the spindle
    2. Weight added or subtracted for equal distribution of wheel weight around its axis of rotation
  B. Dynamic
    1. Wheel rotation true, without wobble or shake
    2. Distribution of corrective weights on both sides of wheel

V. Tire Balance Marks
  A. Symbols Used for Marking Tires
  B. Markings to Line Up with Valve Stem Hole in Rim
  C. Less Accurately Balanced Assembly Marked by Red Dot

VI. Types of Wheel Run-Out
  A. Lateral
    1. Wheel alternately moves in and out from center of vehicle while rotating on its spindle
    2. Causes dynamic imbalance (out of balance)
    3. Checked by pointer near side wall
    4. Run-out not to exceed ⅛ inch
    5. Corrected by remounting tire on wheel or straightening wheel
  B. Eccentric or Radial
    1. Amount of spindle deviation from its center during wheel rotation
    2. Causes static and dynamic imbalance (out of balance)
    3. Checked by pointer near tire tread
    4. Corrected by shaving tread

Section 20: Automotive Brakes

I. Friction
  A. Definition
    1. Dry
    2. Greasy
    3. Viscous
  B. Factors Affecting Friction
    1. Pressure applied or load
    2. Roughness of surface
    3. Type of materials
  C. Types
    1. Static friction (at rest)
    2. Kinetic friction (in motion)
  D. Cause: Surface Irregularities
  E. Application
    1. Brake shoe and brake drum friction
      a. Slows wheel rotation
      b. Stops wheel rotation
    2. Tires to road surface friction
      a. Sliding stop (kinetic)
      b. Rolling stop (static)
    3. Front brakes larger than rear

II. Hydraulics
  A. Definition
  B. Physical Principles of Liquids
    1. Not compressible
    2. Transmit motion
      a. Act as solids under pressure
      b. Action and reaction
    3. Transmit pressure
      a. Pressure equal throughout system
      b. Pressure equal in all directions
      c. Output force equals pressure times area
      d. System pressure equal to input force divided by piston area

III. Hydraulic Brake Fluid
  A. Chemically Inert (Must Not Affect Metal and Rubber Parts)
  B. Must Not Vaporize at High Temperature
  C. Must Remain Fluid at Low Temperature
  D. Must Act as Lubricant
  E. Must Mix Readily With Other Hydraulic Fluids

IV. Types of Brakes
  A. Mechanical
  B. Hydraulic (Four-Wheel)
    1. Shoe
    2. Disk
    3. Caliper or spot
  C. Electric
  D. Air
  E. Vacuum

V. Components of Brake System
  A. Master-Cylinder Assembly
    1. Brake pedal
    2. Brake-pedal linkage
    3. Master cylinder
      a. Body
        (1) Reservoir
        (2) Cylinder

14703

DART LINE ADJUSTMENT FOR LOW BUST

Diagram shows wrinkles and distortion of grain line on ill fitting garment caused by low bust.

Diagram shows bodice front pattern piece with dart line altered for low bust line.

0001

b. Piston
(1) Primary cup
(2) Secondary cup
c. Piston return spring
d. Head nut
e. Check-valve assembly
f. Push rod
g. End boot
4. Dual Master Cylinder
B. Wheel Brake Mechanism
1. Wheel cylinder
a. Cylinder body
b. Pistons
(1) Piston cup
(2) Piston spring
c. Boots
d. Activating spring
e. Bleeder valve
2. Brake-shoe assembly
a. Backing plate
b. Brake shoes
(1) Friction material
(2) Primary shoe
(3) Secondary shoe
c. Anchor pin
d. Hold-down spring
e. Brake-shoe return spring
f. Adjusting mechanism
C. Hydraulic Brake Lines
1. Special type
2. Steel pipe
3. Fittings
4. Flexible hose
a. Front wheel connection
b. Rear axle connection

VI. Hydraulic Brake Operation
A. Application
1. Brake pedal depressed
2. Master-cylinder piston moving forward
a. Compensating port covered
b. Hydraulic fluid trapped in system
(1) Fluid moving in system
(2) Fluid under pressure
3. Wheel cylinder pistons moved outward
a. Activating pin moved outward
b. Brake shoes forced against drums
c. Frictional contact
(1) Heat
(2) Dragging effect
d. Slows wheel rotation
B. Release
1. Release brake pedal
2. Master-cylinder piston returns
3. Brake-shoe return spring activated
4. Brake shoes pulled from drums
5. Wheel cylinder pistons forced inward
6. Liquid returning to master cylinder
a. Pressure dropping
b. Check valve closing
(1) Maintains some pressure in system
(2) Keeps fluid in
(3) Keeps air out

VII. Accessories
A. Hand Brake
1. Drive shaft
2. Rear wheel
B. Power Brakes
1. Purpose
2. Basic principles of operation
C. Self-Adjusting Mechanism
1. Purpose
2. Method of operation
D. Hill Holder
1. Purpose
2. Method of operation
E. Stoplight Switch
1. Mechanically operated
2. Hydraulically operated

Section 21: Purchasing Automotive Parts

I. Make of Automobile
A. Model
B. Year

II. Engine Type
A. Number of Cylinders
B. Cylinder Arrangement
C. Valve Arrangement
D. Cubic-Inch Piston Displacement
E. Horsepower Rating

III. Exact Part to Be Purchased
A. Location
B. Casting Number (if available)
C. Part Number (if available)
D. Design
1. Type
2. Size
3. Description

14704

APPENDIX C

BATTERY TERMINOLOGY

Amperage	The rate of flow of electric current (movement of electrons) in a closed circuit measured in amperes
Battery	A unit (two or more cells connected together) that consumes chemical energy to produce electric energy when needed
Electrolyte	A solution of salts, bases, or acids in water in which the negative and positive plates are immersed
Grid	A framework made of an alloy of lead and antimony that holds an active material
Hydrometer	An instrument used to measure the specific gravity of a liquid
Lead-acid cell	A secondary cell that can be recharged
Negative plate	A grid filled with sponge lead (Pb)
Overcharging	Passing a direct current through a battery that has already been charged to maximum
Positive plate	A grid filled with lead peroxide (PbO_2)
Primary cell	A cell that cannot be recharged
Secondary cell	A cell that can be recharged
Separator	An insulating material made of wood, glass, or rubber that separates the positive and negative plates
Specific gravity	The weight of any volume of a liquid divided by the weight of an equal volume of water or the ratio of the density of a substance to the density of a standard
Sulfation	A process in which lead sulfate coats the plates of a lead-acid battery that has been allowed to remain partially charged
Sulphuric acid and water	The electrolyte of a lead-acid battery
Voltage	Electric pressure, electromotive force (emf) that causes current flow (movement of electrons) when the external circuit is closed

14705

APPENDIX D

ASSIGNMENT SHEETS

Unit 17: Four-Cycle Engines

Explain briefly what takes place during the following strokes:

Intake: _____

_____

_____

_____

_____

Compression: _____

_____

_____

_____

_____

Power: _____

_____

_____

_____

_____

Exhaust: _____

_____

_____

_____

_____

14706

Unit 22: Storage Battery

1. What is the purpose of a storage battery? _____
2. What is the major difference between a storage battery and a cell? _____
3. What is meant by the capacity of a battery? _____
4. What determines the capacity of a battery? _____
5. What are the chemicals used in a conventional automobile battery?

   A. _____ B. _____ C. _____
6. What is a plate grid? _____
7. What is the composition of a plate grid? _____
8. What is meant by the overcharge of a battery? _____
9. What is a plate group? _____
10. The two types of plates used in a lead-acid cell are:

    A. _____ B. _____
11. How are the plates held apart? _____
12. What would happen if the plates touched? _____
13. Why are the separators made of wood, glass, or rubber? _____
14. What is the electrolyte of a storage battery? _____
15. Describe first aid procedures when an electrolyte is spilled on a person: _____
16. Explain what happens when the electrolyte is added to a dry-charged storage battery: _____
17. What is the maximum voltage of a storage battery cell? _____
18. What will occur when the two terminals of a battery are connected through an external circuit? _____
19. From which direction does internal current flow in a battery? _____
20. Describe what occurs when a continuous supply of current has been used from a battery: _____

14707

Unit 23: Magneto and Generator

1. What is a permanent magnet? _____

2. How is a magnet identified? _____
3. What makes up the external magnetic field between the two poles of a magnet? _____
4. In what direction do magnetic lines of force move? _____
5. What are two characteristics of lines of force?

   A. _____

   B. _____
6. What will happen when unlike poles of a magnet are brought together? _____
7. What is magnetic repulsion? _____
8. What is formed around a wire when current is flowing through it? _____
9. How can the magnetic lines of force around a wire be demonstrated? _____
10. State the left-hand rule: _____
11. What is an electromagnet? _____
12. Explain briefly what happens to the magnetic lines of force around two parallel wires that have electric current flowing through them: _____
13. What is the purpose of a magneto? _____
14. How is a magneto driven? _____
15. What is the purpose of a generator? _____
16. How is a generator driven? _____

14709

17. Describe a simple magneto: _____

18. What is the meaning of a "load" in a generator circuit? _____

19. Explain the major difference between a simple direct-current generator and an alternator: _____

20. How is current generated in the windings of an armature? _____

21. What is the source of the current that flows through the field windings? _____

22. What effect does the current flow have on the field of an electromagnet? _____

23. What kind of current is produced in the armature of a direct-current generator? _____

24. How is the generator made to produce more current when its load is increased? _____

25. The three basic parts of a generator are: _____

_____, _____

26. What are slip rings? _____

27. What is a commutator? _____

28. What is the function of brushes in a generator? _____

29. Where are the generator brushes located? _____

30. Why must the output of the generator be controlled? _____

31. What two devices must be used in controlling the output of the generator?

A. _____ B. _____

14710

Unit 23: Rectification and Regulation

1. What is rectification of current? _____

2. Describe a silicon diode rectifier: _____

3. What is half-wave rectification? _____

4. What is full-wave rectification? _____

5. Describe pulsating current: _____

6. What is another name for a cutout relay? _____

7. What device made it possible to adapt alternators for use in automobiles? _____

8. Where is the cutout relay located in the electrical system? _____

9. What are two functions of the cutout relay?

   A. _____

   B. _____

10. Describe a cutout relay: _____

11. When the direct-current generator is in operation, what allows current to flow to the storage battery? _____

12. When the alternator is not operating, what prevents current from flowing from the battery through the generator? _____

13. What causes the contact points of the regulators to close? _____

14. What causes the contact points of the regulators to open? _____

15. Give two results that will cause damage if the generator output is not regulated:

    A. _____

    B. _____

16. What is the purpose of the voltage regulator? _____

14711

17. Does the generator always charge the battery at the same rate? _____

    Explain: _____

    _____

18. To which generator circuit is the voltage regulator connected? _____

    _____

19. As the battery approaches a charged condition, what happens to the voltage applied to the field coils? _____

    _____

20. What is the effect on the magnetic field around the armature as the voltage applied to the field coil changes? _____

    _____

21. What happens when a predetermined voltage is reached at the output terminals of a generator circuit? _____

    _____

22. Describe what happens in the voltage regulator when the output voltage of the generator drops below a predetermined voltage: _____

    _____

23. Why is a voltage regulator referred to as a vibrating voltage regulator? _____

    _____

24. Are current regulators similar to voltage regulators? _____ What is the basic difference? _____

    _____

25. Why is a current regulator described as a vibrating current regulator? _____

    _____

26. Where are the diodes installed in an automobile alternator? _____

    _____

27. Is a cutout relay needed in a transistorized regulator system? _____

    _____

14712

Unit 24: Electricity/Electronics

1. What is the nucleus of an atom? _____
2. A proton in the nucleus of an atom has a _____ charge, and the electron outside the nucleus has a _____ charge.
3. When free electrons collect in one place, a _____ is formed.
4. When these free electrons move from one place to another, it is called _____
5. What two devices in the automotive electric system provide emf?
   A. _____ B. _____
6. What terminals are found on an automobile battery or alternator? _____
7. What substances allow electrons to move freely? _____
8. How is the negative (-) terminal determined? _____
   _____ Positive (+) terminal? _____
9. Why is copper wire a good conductor? _____
10. Why is rubber a good insulator? _____
11. What normally covers a conductor? _____
12. Define voltage: _____
13. If the voltage is increased, what will be the results on the electron movement? _____
14. How is voltage measured? _____
15. What is amperage? _____
16. How is amperage measured? _____
17. What is meant by resistance? _____
18. Why is there more resistance in a small wire than in a large wire? _____
19. Why is the resistance less in a short wire than in a long wire? _____
20. How is resistance measured? _____
21. State Ohm's law (in words): _____

DART LINE ADJUSTMENT FOR HIGH BUST

Diagram shows wrinkles and distortion of grain line on ill fitting garment caused by high bust.

Diagram shows bodice front pattern piece with dart line altered for high bust line.

1468
CAA1

22. What is the basic formula for Ohm's law? _____

23. In the formula, what instruments are used to measure each of the following? _____

E = _____ , I = _____ , R = _____

24. Using Ohm's law, how much voltage is required to force 8 amperes of current through a resistance of 4 ohms? _____

_____

25. Describe a series circuit: _____

_____

26. Describe a parallel circuit: _____

_____

27. What is the advantage of a parallel circuit when a number of units are involved? _____

_____

28. How are switches wired into a circuit? _____

29. What happens to the voltage as it travels through a circuit? _____

_____

14714

ACKNOWLEDGMENTS

The Bureau of Elementary and Secondary Education gratefully acknowledges the assistance of the Central California Automotive Technical Committee in the preparation of *Industrial Arts Power Mechanics.* It was this committee that authored *Industrial Arts Automotive Mechanics,* published by the California State Department of Education in 1964. The Bureau also gratefully acknowledges the assistance of the Statewide Industrial Arts-Science Study Committee, which appraised a set of proposed power mechanics activities involving the application of scientific principles; and the National Power Mechanics Review Committee, which evaluated the experimental edition of *Industrial Arts Power Mechanics.* The teachers, supervisors, or teacher educators who served as members of one or more of these committees are as follows:

California Committee Members

Richard S. Acuna, James A. Garfield High School, Los Angeles; Leslie L. Aldrich, Fresno State College; Cornel Amnasan, California High School, Whittier; Glenn F. Amsberry, San Ramon Valley High School, Danville; Howard Chester Anderson, Orange Coast College, Costa Mesa; Linley A. Anderson, Sylmar High School; Norman Avedian, Clovis High School; Fred A. Baer, Los Angeles Unified School District; William F. Bain, McLane High School, Fresno; Stan C. Barrett, Taft High School; Robert C. Beltzner, Rancho Cotate High School, Petaluma; William H. Bernard, Robert A. Millikan High School, Long Beach; Thomas W. Birch, Luther Burbank High School, Sacramento; Dean A. Bishop, Culver City High School; Ralph C. Bohn, San Jose State College; Clifford J. Boyd, Coronado High School; Gaylord B. Boyer, Modesto City Elementary and High School districts; Joseph J. New Jersey State Dept. of Education, Trenton, Div. of Vocational Education
MF AVAILABLE IN VT-ERIC SET.
Vocational-Technical Curriculum Laboratory, Rutgers University, 4103 Building, Kilmer Campus, New Brunswick, New Jersey 08903 ($1.75).
PUB DATE - Jan71 102p.

DESCRIPTORS - *LABORATORY MANUALS; *TRADE AND INDUSTRIAL EDUCATION; *ELECTRICITY; *ELECTRONICS; VOCATIONAL EDUCATION; INDUSTRIAL ARTS; SECONDARY GRADES; INSTRUCTIONAL MATERIALS; LABORATORY EXPERIMENTS; INDUSTRIAL ARTS

ABSTRACT - Prepared by educators in Warren County schools of New Jersey in cooperation with the Vocational-Technical Laboratory of Rutgers University, this is the first of two laboratory manuals for teacher and student use in teaching the fundamentals of electronics. The contents are designed to challenge prospective electronics technicians through problem-solving techniques concerning basic D-C circuits. The 21 experiments, for use with a basic electronics or electricity textbook, include objectives, material or equipment required, procedure, conclusions, and questions. A materials list, instructions for writing reports, report format, and an accessory kit list are included. Part two is available as VT 012 901, also in this issue. (GEB)

FOREWORD

This Laboratory Manual is written in an attempt to challenge the intellect of the prospective electronics technician. This is accomplished by using the problem-solving technique. The ability to solve problems is a vital prerequisite to the fulfillment of the job classification.

This Laboratory Manual was written to be used in conjunction with a basic electricity or electronics textbook.

Some of the experiments include introductions, as some textbooks do not relate the material content of the theory to a working (laboratory) knowledge of experimentation.

The experiments are arranged in a spiraling order. This provides an increasing level of skill and knowledge each time the general topic is presented.

APPENDIX K

CASE PROBLEMS ON GARMENT ALTERATIONS

The following problems may be utilized as the basis for role-playing situations as a means of stimulating discussion or as part of an evaluation lesson. Each situation presents a fitting problem. Answer the questions in relation to the information given.

1. The seam lines on the skirt do not hang perpendicular to the floor. The skirt wrinkles and the hem line is not parallel to the floor. The customer says all her clothes hang the same way.

   - What is the probable reason for the fitting problem?
   - Can an alteration be made?
   - What steps are needed to correct the fitting problem?

2. The customer's dress fits except in the armhole and shoulder area. The appearance is marred by ripples in the upper sleeve and the shoulder droops onto the arms.

   - What is the cause of the fitting problem?
   - Should the alteration be made?
   - What steps are needed to correct the fitting problem?

3. A customer's skirt fits at the waist and across the hips in the front but the back has ripples at the end of the darts.

   - What is the cause of the fitting problem?
   - What steps are needed to correct the fit?

4. A very slender "flat" young Miss has a dress with a skirt that is loose in the waist and hip area and she would like the dress to fit more snugly.

   - What is the cause of the fitting problem?
   - What steps are needed to improve the fit?

5. A customer has requested that you lengthen an A-line shift on a "permanent press" garment.

   - Should the alteration be made?
   - What steps are needed to make the alteration?

REPORTS

ALL REPORTS ARE TO BE SUBMITTED USING THE FOLLOWING FORMAT:

COURSE TITLE:_____

Experiment Nos._____

TITLE:

DATE PERFORMED
CLASS NO.
INSTRUCTOR

TECHNICAL REPORT SUBMITTED BY:_____

14726

INSTRUCTIONS FOR TECHNICAL REPORT WRITING

I. GENERAL

The following instructions are given to assist the student in making an orderly presentation of the results of the tests performed.

Every laboratory report is to be written with the idea of providing a permanent and complete record of an experiment. Properly prepared reports are of great value for future reference and are to be retained by the student, subject to future inspection. Reports should be completely understandable to another person unfamiliar with your work. They should also be clear to you, long after you have forgotten the details of the work. Sufficient details should be included to enable you or another person to exactly duplicate the experiment.

Reports should be printed in ink or typewritten. Use one side ONLY of 8½" x 11" white quadruled paper (¼" squares) for all needs except graphs. For graphs use standard 8½ " x 11" plotting (graph) paper.

The individual pages of the report should be properly correlated, numbered, and assembled.

The front page must be a standard college title sheet. All information required must be filled in. Names of all members of the laboratory team or group must appear on this page.

II. SKETCHES - DIAGRAMS:

Sketches and diagrams should be in ink. Colored pencil may be used for accenting certain features of the sketches, if desired.

III. CURVES:

Curve sheets must be drawn in ink. Each of the individual curves must be suitably designated. The individual scales on the ordinate and abscissa must be suitably spaced. The units adopted should be clearly designated. The ordinate and abscissa scales should be chosen so that the limits of the ordinate and the abscissa are well within the margins of the curve sheet. The legend on the curve sheet should include:

1. The title of the curve
2. The student's name
3. The date

14727

Coordinate scales should be indicated by heavy lines and suitably designated.

All points of plot should be indicated on the curve sheet.

All curves are drawn as smooth curves. The curves follow the general trend of the points, but do not necessarily pass through all points.

Curves should never be drawn freehand. Always use a straight-edge and/or french curves.

It should be remembered that curves depict the results of the experiment. They are then, necessarily, one of the most important elements of a laboratory report. Precision and care should be used in the choice of scales, location of the points of plot, and the drawing of the curve.

IV. ENGLISH:

Correct English must be used in all report writing. This includes correct spelling and punctuation as well as the proper use of engineering terms. (All reports MUST be written so as to be legible.) Reports will be returned for rewriting if not acceptable.

Personal pronouns such as I, we, etc. should not be used.

V. GRAPHICAL PRESENTATION OF DATA:

1. The overall appearance must be neat and attractive.

2. The graph is to occupy substantially the whole ruled paper.

3. A complete descriptive title is to be lettered more prominently than other items and underlined.

4. The lettering is to be in ink.

5. The lettering must be uniform in size, spacing, and use of capitals or small letters.

6. The minimum height of letters is one space.

7. Plot the independent variable horizontally and the dependent variable vertically.

14728

8. Name the variable and specify all units alongside each axis. Use guide lines for lettering.

9. Use subdivisions of 1, 2, 5, and 10 when choosing scales.

10. Show all points with a cross. Make the cross with a sharp pencil or ball-point pen.

11. If there is more than one set of points, enclose like points with distinguishing marks.

12. The curve or characteristic is the average of the plotted points. It should be smooth, uniform, and continuous. It should have no sharp changes in slope and should be drawn in ink.

13. If more than one curve is plotted on the same graph sheet, they are distinguished by use of color or by dotted or dashed lines.

14. The name of the student and the date should appear in the bottom right-hand corner.

VI. REPORT FORM:

The report must be arranged in the following form:

STATEMENT OF PROBLEM: The object or purpose of the experiment should be a brief, concise statement, usually included in the Laboratory Manual.

CONCLUSIONS: This is a very important portion of the report. It is in this portion of the report that the student makes an analysis of the results obtained and draws any conclusions which are warranted. The results obtained in this report should be compared with other information which is available in trade publications, textbooks, operating manuals, etc. If the results deviate from those which were expected, the student should determine, if possible, the reasons for such variations and include this in this section.

DISCUSSION: A complete analysis of the curves obtained should be made. A satisfactory explanation of the significance of the shape of the curve is required. This should include a comparison between the curves obtained and those expected as well as reasons for deviation, if any.

The student should, at the end of this section, in a brief and concise manner present in numerical sequence, if possible, the conclusions he is able to draw as the results of this report.

14729

METHOD: This should be a brief summary, using the student's own words, of the method actually used in performing the test. It should not be copied from the experiment sheets because of the excessive detail used.

SAMPLE COMPUTATIONS: Show sample calculations, suitably arranged and designated, so that the entire process is clearly indicated. Where several computations of an identical nature have been made, only one (or a sample) need be included.

REFERENCE: The identification of the apparatus, equipment, and materials used in the test should be listed. All data must be properly referenced to Engineering Notebook and must specify Notebook Number and data page.

VII. SUBMISSION OF REPORTS:

Reports are to be completed and handed personally to the instructor during the last laboratory period assigned for the experiment.

It is expected that all reports will be handed in on time.

14730

ACCESSORY KIT COMPOSITION

ITEM	QTY	DESCRIPTION
1	6	Shorting Strip

SILHOUETTE KIT

Suggestions for Using Silhouette Kit

The kit includes five basic figure types, some basic clothing silhouette patterns for the medium build figure, five basic face shapes along with neckline and collar styles to fit the basic dress pattern for the medium figure, and illustrations showing the effect of line on figure types. Some ideas for using the kit are given below.

- Make basic clothing silhouettes for each figure type. Some ideas are provided for the medium figure type.
- Duplicate materials from the kit for each trainee to use for individual projects.
- Use figure types and clothing silhouettes on opaque projector for class discussion.
- Have trainees determine the styles most suited to each figure type by using clothing silhouettes.
- Apply design principles by using skirts, jackets, bodices, collars in different combinations on all figure types.
- Have trainees experiment with figure types by cutting clothes from fabric or wallpaper of different size stripes, figures, and plaids. Show results to class on opaque projector.
- Study the neckline best suited to face shapes by changing faces and necklines on the medium build figure wearing the basic dress.
- Demonstrate the effect of line on various figure types by using colored gummed tape on the basic dress.
- Develop a bulletin board or display case by tracing the figures onto poster board or paper. Costumes can be cut from fabric or wallpaper and tabbed at the shoulders.
- Add felt, flannel, or sandpaper to figures for use on flannel board.

ITEM	QTY.	DESCRIPTION
54	2	Pith balls
55	1	Rod, glass
56	1	Rod, hard rubber
57	1	Pencil, china-marking (black)
58	2	Clip, alligator
59	4	Nut, hexagonal, 6-32
60	4	Post, banana
61	1	Iron filings, 2 oz. package
62	2	Magnet, bar type
64	1	Wire, No. 38 nichrome, 14 inches long
65	1	Cloth, wool
66	1	Cloth, silk
68	1	Stand assembly
69	9	Clip-lead, interconnecting, 5 inches long (black)
70	2	Clip-lead, interconnecting, 10 inches long (black)
71	1	Clip-lead, interconnecting, 12 inches long (black)
72	1	Clip-lead, interconnecting, 12 inches long (red)
73	1	Clip-lead, interconnecting, 30 inches long (black)
74	1	Clip-lead, interconnecting, 30 inches long (red)
75	5	Lead, interconnecting, 8 inches long (black)
76	2	Lead, interconnecting, 8 inches long (red)

14733

EXPERIMENT #1 ELECTROSTATICS

OBJECTIVE

To become aware of the effects and behavior of static electricity.

MATERIAL REQUIRED

Acessory kit

INTRODUCTION

Many electronic devices use the principles of electrostatics. The most common are: the electrostatic voltmeter, loudspeakers, and capacitors.

PROCEDURE

1. Attach one pith-ball string to the top of the stand assembly so that it hangs freely about 4 inches from the point of attachment.

2. Attach the other pith ball on the stand three to four inches to the side of the first ball.

3. Rub a glass rod on the silk cloth, then touch the rod to one pith ball. This charges the pith ball. Now charge the second pith ball.

4. Try to move the two balls together. Notice the effect. Record the result and explain the theory behind your observation.

5. Charge the second ball again, but use a rubber rod rubbed across a wool cloth.

6. Try to bring the balls together. Notice the effect on the balls under these conditions. Record as in step #4.

7. Touch the two balls together, then charge both to the same polarity by repeating step #3. Record your observation as in previous steps.

8. Replace all materials in the accessory kit.

CONCLUSION

Summarize your conclusions.

14734

QUIZ

1. State the Law of charges.

2. What are positive and negative charges?

3. What is an electrostatic field?

4. Write a paragraph concluding the results of the experiments using your own judgment.

14735

EXPERIMENT #2

ELECTRICAL COMPONENTS
AND RESISTOR COLOR CODE

OBJECTIVE

To become familiar with components used in electronic circuits.
To learn to read the Resistor Color Code.

EQUIPMENT REQUIRED

Accessory kit

INTRODUCTION

Before any experimentation work can be started, the student must be capable of recognizing the components used in electronic circuits.

PROCEDURE

1. Select from the accessory kit one of each of the following. Use the Accessory Kit Composition information from pages 5 and 6 as a guide. Go to your text to find any symbols you do not know.

   a. Resistor

   b. Capacitor

   c. Variable resistor

   d. Lamp

   e. Neon bulb

   f. Inductor

   g. Transformer

   h. Vacuum tube

   i. Dry Cell

   Describe the part by marking down the numbers, color, or other marking. Example: Resistor, wirewound, 100,000 ohms.

2. Complete a short paragraph on each of the above components stating its particular characteristics which should include: use in a circuit, construction, symbol, etc.

14736

3. It may be helpful to recognize the physical size of resistors in proportion to their power rating (ability to dissipate heat). The following chart is for your convenience.

FIG. 1A

14737

4. The following figure shows the various methods of color-coding resistors. Refer to Figure D below to learn how to read the values.

A. STRIPE METHOD

FIG. 1B

B. BODY AND DOT METHOD (NO BAND D)

FIG. 1C

14738

C. Color Code:

COLOR	1ST NUMBER	2ND NUMBER	MULTIPLIER	TOLERANCE (PERCENT)
BLACK	0	0	1	
BROWN	1	1	10	
RED	2	2	100	
ORANGE	3	3	1,000	
YELLOW	4	4	10,000	
GREEN	5	5	100,000	
BLUE	6	6	1,000,000	
VIOLET	7	7	10,000,000	
GRAY	8	8	100,000,000	
WHITE	9	9	1,000,000,000	
GOLD			0.1	5
SILVER			0.01	10
NONE				20
	BAND 1	BAND 2	BAND 3	BAND 4

Fig. 1D

D. Example:

Fig. 1E

14740

14739

QUIZ

1. Select 20 different resistors from the accessory kit that use the stripe method of identification. Write the colors down in the order given, then identify the value and tolerance of each.

14740

EXPERIMENT #3 BASIC CIRCUIT DIAGRAMS

OBJECTIVE

To be able to recognize the physical and electrical arrangement of components, in this case, resistive in nature.

EQUIPMENT REQUIRED

Accessory Kit
Breadboard - circuit patching unit

INTRODUCTION

All components and equipment are designed to function both electrically and physically in an orderly arrangement. Recognition of the three basic arrangements is a prerequisite to circuit-building, troubleshooting and repair.

PROCEDURE

1. Construct this circuit on the breadboard.

FIG. 2 A

2. Have your instructor check this circuit and initial your report.

3. Draw a pictorial (picture) diagram of your setup.

4. State the characteristics of the circuit constructed in Step #1.

14741

5. Construct the circuit below and repeat steps 2 through 4.

FIG. 2B

6. Do the same with the circuit below.

FIG. 3

CONCLUSION

The diagrams shown are basic. A series circuit may have some 20 to 30 components. A good idea of what to look for in a series, parallel,or combination circuit is necessary.

QUIZ

1. Have another student arrange a circuit on the breadboard. Draw a pictorial of the setup, then a schematic from this. Have your instructor check to see if they agree. Make sure the battery is not connected in this "prototype" arrangement.

2. Do the same as in step #1 but use other components with the resistors such as: capacitors, coils, bulb, etc.

14741

14742

BASIC FIGURE TYPES

The five basic figure patterns illustrate women with figures that are medium, short and thin, short and heavy, tall and thin,and tall and heavy. These figure types can be used to design various styles of garments. Suggested garment silhouettes for the medium figure are included.

Medium | Short and Thin | Short and Heavy

0781 1471

EXPERIMENT #4 POWER SUPPLY FAMILARIZATION

OBJECTIVE

To become familar with electronic power supplies.

EQUIPMENT REQUIRED

Variable ac, dc power-supply chassis

INTRODUCTION

Safety Note: Do not plug ac line-cord into line power unless told to.

This supply provides both fixed and variable ac and dc voltages to equipment and units under test. Alternating current is delivered to the T_1 and T_3 primaries through the one-ampere line fuses F_1 and F_2. T_1 is commonly called a "variac" since it varies the voltage of the power delivered to the T_2 primary. The ac voltage available from the primary is 0 to 117 volts. This voltage is controlled by the setting of T_1.

Fig. 4

14743

Where it is necessary to have a fixed 117-volt ac supply, you plug into the primary.

Where it is necessary for potentials higher than 117 volts ac, the secondary of T_2 is used (secondaries are normally the right-side windings). The connections to the secondary of T_2 are the two white female banana jacks. This secondary is variable to approximately 330 volts ac, using T_1 as the control.

A low fixed ac voltage of 6.3 volts is obtained from the filament winding of T_3 (FIL). The connections are at the right-hand bottom side of the board. When it is necessary to use high or low direct-current potentials, a semi-conductor (Cr_1 or Cr_2) is used to change ac to dc. This dc potential is available at either (depending on the requirements) the B+, B-, or C- and tap. By switching the M_1 switch to B+ (300 volts) a varying dc potential of 0 to 300 volts will be found available at B+, B- jacks. This voltage will then vary with the T_1 control and read direct on M_1 as to voltage available.

It might be well to note at this time that R_1 and R_3 must always be plugged into the board when working with any dc current.

By switching M_1 to the right side (C + 100 volts dc) and varying R_2, low dc voltages are made available at jacks C+ or C- and the tap.

PROCEDURE

1. After checking the fuses of the power supply, insert the ac plug into the line. Turn on S_1 and vary T_1 (M_1 on B+) until readings are obtained on M_1.

2. Turn T_1 fully counter-clockwise, switch M_1 to C+ and vary R_2 until M_1 responds, indicating the bottom circuit is workable.

3. Turn S_1 off, wait 1 minute, then remove R_3 and R_1. Repeat steps 1 and 2. <u>BE CAREFUL and DO NOT RUSH THIS STEP</u>.

4. Turn off S_1, wait 5 minutes, then replace R_1 and R_3.

CONCLUSION

A power supply can be used to obtain a variety of ac and dc voltages. These voltages may be fixed or variable.

QUIZ

1. Which circuits do the fuses protect and what size are the fuses? What does the fuse size indicate?

14744

2. The available voltages from your unit are:

a_____			ac fixed
b_____			ac "
c_____	to	_____	ac variable
d_____	to	_____	ac variable
e_____	to	_____	dc variable
f_____	to	_____	dc variable
g_____	to	_____	dc variable

3. To the best of your present knowledge, state the functions of each component of the power-supply unit.

Example: F_1 - fuse - protect the circuit from overload.

14745

EXPERIMENT #5

VOLTOHMMETER (VOM)
FAMILARIZATION

OBJECTIVE

To become familar with a meter capable of measuring ac, dc volts, ohms, and dc current.

EQUIPMENT REQUIRED

Power-supply chassis
VOM
Accessory kit
Breadboard

INTRODUCTION

A thorough knowledge of the instrument is a prerequisite to the mastery of that test or measuring device. The following specifications are basic to all VOMs, but apply specifically to the R.C.A. WV38A.

VOLT-OHM-MILLIAMMETER

Type WV-38A

14746

SAFETY PRECAUTIONS

For proper operation, the ground (black) lead of the WV-38A should be connected to the ground of the equipment under test before any connections are made. An important point to remember is that there is always danger inherent in testing electrical equipment. The operator should thoroughly familiarize himself with the equipment under test before working on it. Bear in mind that high voltages may appear at unexpected points in defective equipment.

Experience has shown the following additional precautions to be necessary:

1. It is a good practice to remove the power before connecting test leads to high-voltage points. If this is impractical, be very careful to avoid accidental contact with equipment racks and other objects which can provide a ground. Working with one hand in your pocket and standing on a properly insulated floor lessens the danger of shock injury.

2. Filter capacitors may store a charge large enough to be lethal. Discharge all filter capacitors before attaching test leads.

3. Remember, leads with broken insulation provide an additional hazard at exposed points along the leads. Check your test leads for frayed or broken insulation before working with them.

4. To lessen the danger of accidental shock, disconnect the test leads immediately after the test is completed.

5. Remember, the risk of severe shock is only one of the possible hazards. Even, a minor shock can place the operator in jeopardy of more serious injury, such as a bad fall or contact with a source of higher voltage.

6. The experienced operator continuously guards against injury and does not work on hazardous circuits unless another person is available to assist in case of accident.

The RCA WV-38A is a lightweight, compact, rugged, all-purpose ac measuring instrument. It is designed to measure the rms values of sine-wave voltages from 0.1 volt to 5000 volts, dc voltage from 0.005 volt to 5000 volts, dc current from 1 microampere to 10 amperes, resistance values from 0.2 ohm to 20 megohms, and decibels from -20 DB to + 50 DB.

14747

SPECIFICATIONS

Electrical

DC Voltmeter (at full scale):

Ranges . . . . . 0 to .25, 1.0, 2.5, 10, 50, 250, 1000, 5000 volts
Input resistance 20,000 ohms per volt
Circuit loading 50 microamperes bleeder
Accuracy ±3%

AC Voltmeter (at full scale):

Ranges . . . . . 0 to 2.5, 10, 50, 250, 1000, 5000 volts
Input Resistance 5000 ohms per volt
Circuit loading 200 microamperes bleeder current
Accuracy ±5%
Frequency Response (reference 1000 cps) flat within 1/2 db from 10 cps to 50 kc on the 25-, 10-, and 50-volt ranges.

DC Current (at full scale):

Ranges . . . . . 0 to 50 microamperes
0 to 1 milliampere
0 to 10 milliamperes
0 to 100 milliamperes
0 to 500 milliamperes
0 to 10 amperes

Insertion Loss 0.25 volt
Accuracy ±3%

DC Ohms:

Ranges	Scale Ends	Center Scale	Full-Scale Currents
R x 1	2,000	12 ohms	120 ma
R x 100	200,000	1200 ohms	1.2 ma
R x 10,000	20,000,000	120,000 ohms	0.006 ma

Accuracy ±3% of pointer position for exact value

Internal Batteries:

R x 1 1 1/2 volt D Cell
R x 100 1 1/2 volt D Cell
R x 10,000 4 Penlite Cells in series with D cell, 7 1/2 volts

14748

AF Output (at full scale):

Ranges	0 to 25, 10, 50, 250 volts
Input Resistance	5000 ohms per volt
Circuit Loading	200 microamperes
Accuracy	± 5%

Note:

An internally connected .01 µf blocking capacitor permits output measurements in presence of dc voltages. If measurements are made in high-impedance circuits (e.g. electron-tube plates) very little error results. Where measurements have to be made in low-impedance circuits, with dc voltage present, an electrolytic capacitor of 10 µf or higher should be connected externally in series, and the measurement made as a regular ac voltage.

Decibel Levels (Zero DB is 1 milliwatt in 600 ohms):

2.5 V range	-20 to + 10 db
10 V range	- 8 to + 22 db
50 V range	+ 6 to + 36 db
250 V range	+ 20 to + 50 db

(May be read on Output or AC positions)

METER MOVEMENT

The WV-38A has a large 5 ¼ inch, extended-view meter housed in a clear plastic case. The case is sealed to prevent foreign matter from entering the meter and interfering with its operation.

SCALES

There are five separate scales on the meter. The top black scale is used when measuring ohms. The second black scale is used to read dc voltages and currents. The two red scales are used when measuring ac voltages, the lower one being used only for the 25-volt range. The bottom scale on the meter is used for decibel measurements. A chart, located at the lower right-hand corner of the scale, is used when making decibel measurements.

RANGE SWITCH

The Range Switch, located at the center of the control panel, has 12 positions. The Range Switch may be turned in either direction to obtain the function and range desired.

14749

14749

AC-DC SWITCH

The AC-DC Switch, located at the upper left-hand corner of the control panel, has three positions. It should be set in the AC position for all ac and Output voltage measurements. For all other measurements it is normally set in the DC position. The DC position is used to reverse the polarity of the test leads when the black lead is plugged into the COMMON jack.

The AC-DC Switch does not function when the +25V 50μa or +1V 50 μa jacks are being used, nor does it function in the -10A or +10A positions.

PANEL JACKS

There are nine jacks located on the control panel. The jacks are designed for trouble-free, low-resistance connections. The test leads must be inserted into the proper jacks to obtain the circuit and range desired for each function of the WV-38A.

OPERATING SECTION

Zero Setting of Pointer

The pointer of the meter must indicate zero when the WV-38A is in the normal operating position. If the pointer does not indicate zero, the adjustment screw, located at the lower center of the meter cover, should be readjusted.

USE OF RANGE AND METER SCALES

The meter scales on the WV-38A have been designed to provide ease of operation and quick readability over a wide range of measurements. The scales have been grouped according to the type of measurement for which they are used.

Because of the wide number of measurement ranges provided on the WV-38A, it is often possible to take voltage or resistance readings on two ranges and scales. For the greatest accuracy in voltage and current measurements, always use the range which will provide an on-scale reading which is nearest to the full-scale point. For example: 48 dc volts can be read from either the 50-volt or the 250-volt range. Because the 50-volt range will provide a reading nearest the full-scale point, the 50-volt range should be used. This general rule applies to all ac and dc voltage ranges. For resistance measurements, however, the range selected should be the one which provides the reading nearest the center of the scale. The WV-38A provides the most accurate ohms-readings at mid-scale points.

14750

For some measurements it will be necessary to use a multiplying factor with the scale to obtain the correct reading. The required multiplication is indicated by the setting of the range switch. For example: when the range switch is set to the 100-V position for voltage measurement, the 0 to 10 scale is used, but the reading is multiplied by 100.

CAUTION

When making voltage or current measurements, it is a good practice to make a trial measurement at a higher range setting than is considered necessary. Repeated overload may destroy the meter movement or impair the accuracy of indications.

FIGURE 4. D-C VOLTAGE MEASUREMENT

DC Voltage Measurement (See Fig. 4)

1. Set the AC-DC Switch to the "+DC" or "-DC" position as required.
2. Set the Range Switch to a position considerably higher than the voltage to be measured.
3. Plug the black test lead into the "COMMON" jack on the control panel.
4. Plug the red test lead into the "+" jack on the control panel when the 2.5V, 10V, 50V, 250V, or 1000V range is used.
5. Connect the test leads to the voltage source to be measured.
6. Reset the Range Switch to a position which gives a suitable pointer deflection.
7. Read the dc voltage from the scale corresponding to the range selected.

14751

For the .25 Volt, 1 Volt, and 5000 Volt Ranges:

Note: When using the .25V and 1 V jacks, the Function Switch must be set to the "+DC" position. Meter polarity must be observed by applying the red test lead to the positive circuit point and the black test lead to the negative circuit point.

8. To use the .25-volt range, set the Range Switch to the 2.5 V position and plug the red test lead into the "+.25 V/50 µA" jack.
9. To use the 1-volt range, set the Range Switch to the 1.0 V position, and plug the red test lead into the "+1 V" jack.
10. To use the 5000-volt range, set the Range Switch to the 5000 V position, and plug the red test lead into the "DC 5 KV" jack.

FIGURE 5. A-C VOLTAGE MEASUREMENTS

AC Voltage Measurement (See Fig. 5.)

1. Set the AC-DC Switch to the AC position.
2. Set the Range Switch to a position considerably higher than the voltage to be measured.
3. Plug the black test lead into the COMMON Jack on the control panel.
4. Plug the red test lead into the + jack on the control panel when the 2.5 V, 10V, 50V, 250V, or 1000V range is used. When the 5000V range is used, the red test lead must be plugged into the "AC 5 KV" jack.
5. Connect the test leads in series with the current flow to be measured.
6. Reset the Range Switch to a position which gives a suitable deflection point.
7. Read the ac voltage from the scale corresponding to the range selected.

14752

BASIC FIGURE TYPES

Tall and Thin

Tall and Heavy

1472

FIGURE 6. D-C CURRENT MEASUREMENTS

DC Current Measurement (See Fig. 6)

1. Set the AC-DC Switch to the +DC or -DC position as required.
2. Set the Range Switch to a position considerably higher than the current to be measured.
3. Plug the black test lead into the COMMON jack on the control panel. This is for all ranges with the exception of the 10 AMPS range.
4. Plug the red test lead into the + jack on the control panel for all ranges with the exception of the 10A and 50μA ranges.
5. Connect the test leads in series with the current-flow to be measured.
6. Reset the Range Switch to a position which gives a suitable point deflection.
7. Read the dc current from the scale corresponding to the range selected.
8. To use the 50μA range, set the Range Switch to the 50 μA position and the Function Switch to +DC position. Plug the red test lead into the +25 V/50μA jack. The meter polarity must be observed by applying the red test lead to the most positive current connection and the black lead to the less positive (negative) connection.
9. To use the 10 A range, plug the black test lead into the -10A jack and the red test lead into the +10A jack. On this current range the AC-DC Switch must be set to the +DC position, and the Range Switch set to the 10A position. Meter polarity must be observed by applying the red test lead to the most positive circuit connection and the black lead to the other circuit connection.

14753

PROCEDURE

1. Assemble the following circuit on the breadboard. (Do not energize the power supply.)

FIG. 7

2. Set R_2 counterclockwise, M_1 to CT (Makes the bottom scale of M_1 applicable, 0-100).
3. Turn on S_1, adjust R_2 until M_1 reads 10 volts (1/10 of full scale).
4. Measure (VOM) the dc voltage present between points A and D. The Tap is negative. If the VOM does not read at all, call your instructor. If it reads either slightly high or low, adjust R_2 until the VOM reads 10 volts precisely.
5. Each resistor, being the same value, should develop 5 volts, for a total of 10 volts. Measure points A to B and B to C. Knowing that the negative side of the VOM should always be connected to the "Low" side of a circuit, and that the Tap is Low, make sure that the lowside of the meter is connected to B then C in the order of checking. Record all pertinent information.
6. Calculate the meter resistance (Rm) at this voltage.
7. Turn S_1 off and assemble the following circuit on the breadboard.

14754

FIG. 8

8. Place the VOM on a scale capable of reading about 10 milliamperes dc.
9. Turn on S_1 making sure that M_1 still holds at 10 volts dc. Readjust if necessary.
10. Record the current through the ammeter.
11. When using the VOM as an ohmmeter (measuring the value of dc resistance), there are certain conditions to be met. The circuit or component being measured must be de-energized (no ac or dc power applied). Internal batteries in the VOM furnish all the power necessary to measure the component or circuit.
12. Procedure for ohms measurement.
    a. Set the Function Switch to the +DC position.
    b. Set the Range Switch to the appropriate position.
    c. Plug the black test lead into the COMMON jack on the control panel.
    d. Plug the red test lead into the + jack on the control panel.
    e. Short the test leads together and adjust the ZERO OHMS control until the pointer indicates "0" (full scale clockwise).
    f. Connect the test leads to the resistance to be measured.
    g. Reset the Range Switch if necessary to a position which gives a suitable pointer deflection. If this is necessary, repeat steps e and f before proceeding with step h.
    h. Read the resistance from the OHMS scale, and multiply by the range factor.

14755

CAUTION:

Low-current, low-resistance devices, such as thermocouples and meter movements, may be damaged unless a range above "R x 1" is used, because the WV-38A applies up to 1.5 volts across the resistance under measurement when the range selector is set at "R x 1".

To facilitate checking the front-to-back resistance ratio of electrolytic capacitors and semiconductor devices, the test lead polarity can be reversed by setting the Function Switch to the DC position.

13. Assemble the circuit shown below.

FIG. 9

14. After "Zeroing" your ohmmeter on the range you expect the reading to fall into, measure and record points A to B, B to C, and A to C.
15. Try changing the Range Switch to some other range. Record the range used and accuracy obtained in comparison to step #14 readings.

Always zero the meter after switching ranges.

Ex. R x 1 to R x 100 to R x 1000

14756

CONCLUSION

The VOM is a versatile instrument with several functions.

It can be used to measure most voltages and resistances with a good degree of precision.

QUIZ

1. Which range would be used when measuring:

   a. 60 volts dc
   b. 3 volts dc
   c. 8 ma
   d. 300 ma
   e. 2.7K ohms
   f. 56K ohms

2. Explain "meter sensitivity".
3. When measuring a particular value of resistance, it was found that the meter's pointer did not move from the static position. List the possible causes of this condition in their order of probability.

14757

14758

EXPERIMENT #6 OHM'S LAW - SERIES

OBJECTIVES

To establish the fundamental relationship of Ohm's Law in a series circuit.

To gain a working knowledge of series circuit characteristics.

EQUIPMENT REQUIRED

Power supply
Breadboard
Accessory kit
VOM

PROCEDURE

1. Construct the following circuit on your breadboard. (Leave S_1 off.)

FIG. 10

2. Calculate E R_1, E R_2, I R_1, I R_2, I_1 and R_T.
3. Turn on S_1 and adjust R_2 to assure 50 volts output.
4. Measure E R_1 and E R_2.
5. Disconnect power (S_1 off) and open the circuit between points B and C. Insert a milliammeter.
   (All current measuring devices are called ammeters. It is not wrong to call a milliammeter an ammeter even though ma current is expected). Make doubly sure that the Range is sufficient, as per your calculations.

14758

6. Apply power; measure and record I_T.
7. Explain the differences found between the theoretical and the actual currents.
8. Construct the following circuit and make a full report as per step 1 to 7.

FIG. 11

9. Calculate E R_1 through E R_5, I R_1 through I R_5, and R_T.
10. Measure all calculated values of step 9.
11. Record any differences, if significant.
12. Calculate Total Power, as well as P R_1 through P R_5.
13. Which of the resistors, if the circuit were overloaded, would most probably overheat and burn open first?
14. Does $R_T = E_T/I_T$?
15. State Ohm's Series Circuit Laws, using the short form. Ex: $R_1 = R_2 = R_3$ etc.
16. Calculate the value of R_T for the following circuit.

FIG. 12

14759

17. Construct the circuit, combining resistances to "make up" the value of R_x. Insure, through calculations, that PR_x is sufficently high.
18. Measure ER_x, E bulb, and I_T.
19. Do the theoretical and measured values agree?
20. If the source voltage (50V) were doubled, what would be the new value of R_x?
21. Construct and measure the circuit described in step #20.

CONCLUSIONS

Most loads or devices in circuitry require a minimum and maximum of power to operate properly. Sometimes a power source must be divided correctly or the load will have either:

a. not enough power to operate;
b. too much power and be damaged.

QUESTIONS

1. Explain how the 7-watt load would function if R_x were accidently shorted out or burned open.
2. What would be the function of the components (resistors) in the circuit if the 7-watt lamp were a 7-watt transistor amplifier?

14760

EXPERIMENT #7 OHM'S LAW - PARALLEL

OBJECTIVES

To achieve a workable knowledge of parallel circuit connections and circuit laws.

MATERIAL REQUIRED

Power Supply
Breadboard
Accessory Kit
VOM

PROCEDURE

1. Construct the following circuit:

R_1 = 1K - 5W
R_2 = 1K - 5W
R_3 = 100K - 1W

FIG. 13

2. Calculate R_T, I_T, I R_1, I R_2, E R_2, and PR.
3. Measure and record all but P_T, explaining any significant differences noted.
4. State the parallel circuit laws in short form.
5. Remove R_2 and replace with a 10K-1W resistor.
6. Calculate and measure the new circuit conditions.
7. Add R_3, then repeat step #6.
8. Review your findings, using any pertinent information gained through the experiment.
9. Design a parallel circuit with one branch containing a 7-watt light bulb and the other branch using 5 watts of power.
10. Build and test the circuit in #9.

14761

14761

CONCLUSIONS

Parallel circuits are widely used. Some of the most elaborate equipment (radar, machine logic control, computers, T.V. and radio) use many of their control and power output sections in parallel (or shunt) due to the advantages. DO NOT proceed to the next experiment until you have a full understanding of the series and parallel circuit.

QUESTIONS

1. What determines the maximum total power parallel branches may use?
2. State the formulas that can be used when calculating total resistance in a parallel circuit. Which would be most commonly used?
3. What would be the result, in a well-designed circuit, if the source voltage were doubled on R_T?
4. If, in a parallel circuit, it was thought that one of the resistive branches was not passing any current, what method could be used to find this trouble? Explain your answer in detail.
5. What would be the effect on the circuit parameters if one branch were to short out? Explain your reasoning.

14762

STAT 1473

EXPERIMENT #8 OHM'S LAW - COMPLEX I, II, AND III

OBJECTIVES

Most pieces of elaborate equipment use both series and parallel circuit arrangements, in what is called complex circuits. By applying both circuit laws to the individual branch or string, a reasonable understanding of the circuit can be realized.

MATERIAL REQUIRED

Power supply
Breadboard
Accessory kit
VOM

PROCEDURE PART I

1. Construct the following circuit.

FIG. 14

2. Calculate and measure E R_1, E R_2, I_T, and R T_2.
3. Add R_3, then calculate and measure E R_1, E R_2, E R_3, I R_1, I R_2, I R_3, I_T, and R_T.
4. Make a comparison between steps 2 and 3, explaining the effect on the circuit of the addition of R_3.
5. Change R_3 to a 1K ohm-1 watt resistor and compare the values of the circuit with the original values.
6. Do the circuit laws agree with the actual findings? To what extent?

14763

PART II (Turn in as a separate experiment)

1. Construct the following circuit.

$R_1, R_6 = 1K - 5W$ $R_3 = 1K - 1W$

$R_2 = 560 - 1W$ $R_4, R_5 = 2.2K - 1W$

FIG. 15

2. Calculate ALL INDIVIDUAL values of E, I, R, and P.
3. Measure all measurable values.
4. Calculate R_T from point C to E with A to B shorted.
5. Measure R_T from point C to E with A to B shorted.
6. Calculate and measure R_T from point E to D.
7. Explain any significant differences in the above.

14764

PART III (Turn in as a separate experiment)

1. Construct the following voltage divider.

R_1=1K-5W	R_5=4.7K-1W
R_2=2.2K-1W	R_6=15K-1W
R_3=5.6K-2W	R_7=18K-1W
R_4=10K-1W	R_8=22K-1W

FIGURE 16

2. R_6, R_7, and R_8 represent power-consuming units or devices such as transistor or vacuum-tube circuits.
3. Calculate and measure all values of E, I, and R_T. Calculate all PRs and P_T.
4. Measure all circuit potentials from the reference point D to all other points. Explain the negative readings.
5. Repeat step #4 for point F.

CONCLUSIONS

By a predetermined arrangement of components, it is possible to "bleed" a source value (such as 100 V) down to values required by specific units, delivering both positive and negative values that some loads require. By changing the reference point or the source, a new set of conditions exists. Part III is one of the most useful yet complicated dividers used. A good working knowledge of complex circuits must be gained to advance. Do not proceed unless you understand this unit.

14765

QUESTIONS

1. In Part III, by moving the reference to point E, what is the voltage across R_8? Why is this true?
2. In Part III, by moving the reference to point A, what happens to the polarity of R_1 through R_5?

14766

EXPERIMENT #9 ELECTROMAGNETIC FORCE

OBJECTIVE

To observe the effects of a magnetic field produced by a current carrier.

MATERIAL REQUIRED

Accessory kit
Test leads

PROCEDURE

1. Breadboard the following circuit.

FIG. 17

2. Position a compass at point A so that the needle and X Y are parallel. (Keep S_1 open)
3. Close S_1 and note the direction the compass is deflected. Explain.
4. Open S_1 and position the test lead 90° to the compass needle.

14767

FIG. 18

5. Close S_1 and observe the results.
6. Take a sheet of paper and scatter some iron filings over the inner third of the paper. Lay the 1 foot test lead over the filings.
7. Close S_1 lift the test lead up slowly. Observe and explain the results after opening S_1.

CONCLUSION

The passage of current along a conductor has many side effects, some useful, others deterimental. Most present-day generators and alternators work on this principle.

QUESTIONS

1. What form do the lines of force take when current passes through a conductor? (Refer to your text for information)
2. If the current in a conductor rises, does the amount and/or the strength of the lines of force increase or decrease?

14768

EXPERIMENT #10 AMMETERS - DC

OBJECTIVES

To develop the skills necessary to use ammeters.
To learn the electrical make-up of an ammeter.
To learn to construct an ammeter in an emergency, using a basic meter movement.

MATERIAL REQUIRED

Basic multimeter circuit board
Accessory kit
VOM (DC, ma)
4 - #6 dry cells (E_{bb})

PROCEDURE

1. Set up the basic circuit on the multimeter board, making sure that R_2 is set to minimum resistance before the battery is engaged.

FIG. 19

2. Adjust R_2 until the meter M_2 reads full scale. Disconnect E_{bb}.

14769

3. Without moving the R_2 slider, remove R_2 from the circuit and measure its finite value. Record as R_m.
4. Place R_2 back into the circuit then explain why this variable should be called R_m (M = meter).
5. Divide the M_1 reading by two. Call this I_m and record. Why?
6. Connect the following circuit.

R_1=1.5K-1W E_{bb}=3V DC

R_2=500 VARIABLE M_1= 0 TO 10 MA

FIG. 20

7. Before closing S_1, calculate the total possible current in this circuit (Exclude R_2).
8. Calculate the value of R_2 necessary to limit the current through R_m to the maximum "safe" point. Record and set R_2 to this value.
9. Close S_1 and observe the R_m's indication. Record and explain any variations observed.
10. From the above investigation, it should be obvious that as E_{bb} increases, I_T increases. Calculate the R_2 (R_x) value for the following sources:
    a. 4.5 v
    b. 6.0 v
    c. 9.0 v
11. Substitute the R_x values on the schematic that will make the meter capable of reading:
    A = 0 to 1 amp
    B = 0 to 100 ma
    C = 0 to 10 ma
    D = 0 to 1 ma

14770

* USE THE VALUE OF R_M FROM THE PREVIOUS INFORMATION

FIG 21

12. If I_m was doubled, for a full-scale deflection:

    R_{xa} = _____
    R_{xb} = _____
    R_{xc} = _____

13. Give the schematic of a circuit for a meter movement that takes 50μ (micro) amperes for full-scale deflection. This should be capable of switching to:

    0 to 50 μa, 500 μa, 1 ma, 10 ma, and 1 ampere.

CONCLUSION

A meter must have a circuit to divide the current if it is to be used to measure currents greater than the meter movement can carry.

QUIZ

1. What type of meter movement is used in the multimeter board?
2. What is a meter-movement shunt?
3. Explain why movements generally "rob" the circuit of some power when placed in series. Would they or could they be placed in parallel?

14771

BASIC CLOTHING SILHOUETTES FOR MEDIUM FIGURE

V-neck Dress

Square Neck Tunic Dress

Basic Dress

Eisenhower Jacket

Bertha Collar Jacket

Double-breasted Coat

Double-breasted Jacket

1474

CONCLUSIONS

The experiment should have proven that a unidirectional meter-movement will measure alternating current if a device is used or switched into the circuit that converts ac into dc.

QUIZ

1. Why is R_1 placed in the circuit?
2, How could this meter be extended to measure 63v, 630v or .63v?

14773
14773

EXPERIMENT #12 VOLTMETERS

OBJECTIVE

To gain a better working knowledge of voltmeters by investigating the relationship between sensitivity and multipliers.

MATERIAL REQUIRED

Multimeter panel
Power supply
Breadboard
VOM
Accessory kit

PROCEDURE

1. Construct the following circuit. Leave S_1 off and R_3 slider at minimum resistance. (It must be determined how much current will cause full-scale deflection of M_1 and what E_m is at this time.)

FIG. 22

2. Place M_2 on the 2.5v dc scale (observe polarity) and turn on S_1 power.

14774

3. Adjust R_2 (power supply chassis) until M_1 (P.S.) reads 100 volts dc.
4. Adjust R_3 until M_1 (Multimeter panel) reads full scale.
5. Read and record M_2 voltage. (External voltmeter). This is E_m full scale.
6. Calculate the multimeter-panel voltage-sensitivity rating from previous data.

$$SR = \frac{R_m}{E_m}$$

where SR is the amount of resistance necessary to limit the current through the meter to full-scale reading with one volt applied.

Placement example:

FIG. 23

7. In determining the value of multiplier resistors, calculate the value necessary to extend the voltmeter to 10v

$$R\ mult = \frac{E\ full\ scale}{I\ full\ scale} - R_m$$

8. Consider the multiplier resistor, using the "black box" method.

14775

Example

FIG. 24

If R_m can develop, let us say, no more than .1 volt across it, while passing no more than 1 ma of current, the black box must develop 9.9v, or 10.0v minus .1v. The value of R box (R multiplier) is $R + \frac{E}{I}$, or 9.9K when used with a 10-volt source.

FIG. 25

9. Calculate R multiplier necessary to extend the meter to read:

A.	50v	C.	500v	E.	5v
B.	100v	D.	1000v	F.	25v

14776

10. Construct the following circuit to verify our theory.

Fig. B

11. After turning the R_2 slider (patching unit) to the bottom position, adjust R_2 (+) for a power supply reading of 100 v.
12. Adjust R_2 (patching unit) until M_1 (multimeter panel) reads maximum.
13. Measure E_m and E source (external multimeter - BP to R_3 bottom).
14. Compare these readings to your calculations.

AC MEASUREMENTS

1. Construct the following circuit, but do not apply power.

Fig. C

2. Calculate the multiplier resistor needed to produce a 0-300 volt ac voltmeter. If the calculated size is not 300K, replace the 300K resistor with your calculated value.

14777

3. Set T_1 variac, fully counterclockwise.
4. Apply power (S_1 on) and slowly turn T_1 until M_1 (multimeter panel) reads full scale.
5. Compare the external multimeter (source) to M_1 (multimeter panel). Record the results.

CONCLUSIONS

When a basic D.M. moving-coil meter movement is connected in series with a multiplier resistor and a source voltage, the instrument is called a series dc voltmeter. With the addition of an ac-to-dc converter, the meter will measure ac voltages.

QUIZ

1. A 30-volt dc voltmeter has a terminal resistance of 10K. What is the amount of current necessary for a 50% scale deflection? A full-scale deflection?
2. Why is a voltmeter scale linear?
3. Why must ac be converted to dc when used in most meter movements?

14778

EXPERIMENT #13 OHMMETERS

OBJECTIVE

To construct the two basic types of ohmmeters, testing resistances to measure the validity of the meter.

MATERIAL REQUIRED

Multimeter (VOM)
Multimeter panel
Patching unit
Accessory kit

PROCEDURE

1. Construct the following circuit (series ohmmeter).

Fig. D

2. Be sure that BT_1 (1.5v) is properly polarized, then calculate R_T and I_T of the circuit, using 2500 ohms as the value in your calculations.
3. If I_m does not exceed 1 ma, momentarily touch the panel meter leads together, adjusting "ohms adjust" until M_1 reads maximum. (Do not move this potentiometer from this position, as the circuit is now calibrated.)
4. Remove BT_1 from the circuit, and measure the 1K resistance and the ohms-adjust separately. Do not measure across the meter, or it will burn out. Now add R_m to the combined series resistance and divide this value into the BT_1 voltage. This should be I_m, which was found in preceding experiments.

14779

5. Replace B T_1, then take the panel meter leads and place them across R_1 on the breadboard. I_m should be half the previous I_m. This should prove that R_T has now been doubled, indicating half current.

6. Measure and record the readings obtained when measuring across: (Refer to the circuit patching unit diagram on previous page)

R_2 = _____
R_4 through R_2 = _____
R_3 through R_4 = _____

7. Construct the following circuit.

R_S = 160 R_2 = 2.5K VAR.
R_1 = 1K BT_1 = 1.5 V

FIG. 26

8. Figure 26 is an alternate method of constructing a series ohmmeter using a meter shunt. This allows I_T to double while I_m remains constant. Adjust R_2 for full-scale deflection with the meter leads touching. Release.

9. Calculate the R_T and I_T of the circuit (consider the leads connected).

10. By calculation it is found that with the addition of R_5, in this case 160 ohms, the basic meter has been extended to read M x 10 ($160 \approx 1/10\ R_T$).

11. Measure all the previous points covered in step #6. Multiply all readings by the range multiplier (x10) to determine the actual resistance.

14780

12. Replace the 160-ohm resistor with a 16-ohm resistor. Zero the meter in as in step #3.

13. Read R_3, R_4, and R_5. The meter is on the Rx1 scale.

R x .1 = 1.6 ohm
R x 1 = 16
R x 10 = 160
R x 100 = 1600
R x 1000 = 16K
etc.

CONCLUSION

The ohmmeter is a direct-reading device but may be extended to read <u>any</u> value with the use of proper shunt or series resistances. The meter is also capable of applying power to the part or circuit under test. Never work an ohmmeter into a "live" circuit.

QUIZ

1. Compute the current-limiting resistance required to produce a full-scale deflection for a series ohmmeter having a 1 milliampere meter movement, R_m = 100 ohms, with a source of 6 volts rather than 1.5v.
2. Calculate the shunt resistance necessary when using a 50 μv (MICROAMP) movement with R_m = 100 and a source of 3v (B T_1).

14781

EXPERIMENT #14 CELLS

OBJECTIVES

To determine the condition of a primary cell by measurement of its internal resistance.

To learn how to combine cells for a variety of potentials.

MATERIAL REQUIRED

Multimeter
Accessory kit

PROCEDURE

1. Set the VOM on the 2.5-volt scale and measure the E_{NL} (no-load voltage) of a No. 6 dry cell. Record.
2. Connect a 2.2-ohm resistor "across" this cell and measure E_L (loaded voltage). (Disconnect as soon as possible because the current will approach 1 ampere.)
3. Calculate R_I (internal resistance of the battery), using the formula below.

$$R_I = R_L \left(\frac{E_{NL} - E_L}{E_L}\right)$$

4. Repeat steps 1 to 3 for at least three other cells.
5. Compare the resistances by placing them in a chart form.
6. Select, in order, the most efficient cells, using R_I as the determinant. (Bad cell, R_I = infinity)
7. Connect the 4 cells in series, in parallel, and then in combination as shown in figure E.
8. Record all measurable information.
9. Sum up all characteristics of series-connected, parallel-connected, and combination-connected cells.
10. Design a circuit which has the ability to supply power to a 1-watt lamp rated at 3 volts, dc. Four 1½-volt batteries are available, each capable of delivering 100 milliamperes.

CONCLUSION

Cells are combined to form batteries capable of delivering either high-output voltage and low current or low-output voltage and high current, depending on the requirements of the load circuit.

14782

BASIC FACE SHAPES, NECKLINE STYLES, AND COLLAR STYLES

Face shapes are designed to fit the medium figure type. An oval face is considered ideal; therefore, attempt to create this illusion for other face shapes by using appropriate neckline and collar styles. Various neckline and collar styles given are planned for the medium figure pattern wearing the basic dress.

BASIC FACE SHAPES

NECKLINE STYLES

Fig. E

QUIZ

1. If two cells, one 1½v and the other 3 volts, are connected in parallel, what would a voltmeter measure when placed across these two batteries? 1½, 3, or 4½ volts?
2. Define polarization. How can it be decreased?
3. Why does a primary cell have a limited "shelf" life?
4. What is a battery?

14783

EXPERIMENT #15 KIRCHHOFF'S LAW

OBJECTIVE

To verify, through experimentation, Kirchhoff's voltage and current laws. To apply the voltage law in circuitry.

MATERIAL REQUIRED

Power supply
Breadboard
Multimeter
*VTVM (Vacuum tube voltmeter)
Accessory kit

*Read manufacturer's instruction sheet before attempting to use this instrument.

PROCEDURE

1. Construct the following circuit, with S_1 off and T_1 and R_2 fully counterclockwise.

Fig. F

2. Turn on S_1 and adjust R_2 until C+ = 45v.
3. Measure and record the voltage drop across R_1, R_2, and R_6. Do these add up to give the applied voltage?
4. Measure the voltage developed across R_1, R_3, R_4, R_5 and R_6. Together they make up a closed loop. Explain how Kirchhoff's voltage law applies to a closed loop such as mentioned in steps 3 and 4.
5. Use a VTVM to test the two closed loops, comparing it to the VOM readings.

14784

6. Measure $I\ R_6$, $I\ R_2$, and $I\ R_5$ with the VOM.
7. If $I\ R_6$ is the current to junction "B", does $I\ R_2 + I\ R_5$ add up to $I\ R_6$?
8. Measure $I\ R_1$ through $I\ R_3$. Does $I\ R_2 + I\ R_3$ add up to $I\ R_1$? Explain how Kirchhoff's Current Law applies in this step.
9. Using the circuit built on the patch panel, write the algebraic current and voltage sign path.

Ex:

$$-I\ R_1 + I\ R_2 + I\ R_3 = 0$$
$$-10 + 5 + 5 = 0$$

CONCLUSION

Kirchhoff's voltage and current laws use deductive reasoning in analyzing complex circuitry by other means than Ohm's law. Ohm's law is <u>never</u> incorrect, but sometimes it is a slow method of analysis.

QUIZ

1. In what direction is current assumed to flow, when using the laws?
2. A voltage traced in the direction of assumed current-flow is preceded by a _____ sign, whereas a voltage drop traced against the assumed direction of current-flow is preceded by a _____ sign.

14785

EXPERIMENT #16 SUPERPOSITION THEOREM

OBJECTIVE

To solve complex circuits involving two or more sources of voltage or current.

MATERIAL REQUIRED

Breadboard
Power supply
VOM
Accessory kit

INTRODUCTION

In any resistive network containing several power sources, the current through any resistor can be determined by algebraically adding individual currents caused by each source acting alone. During the individual determinations all other power sources are considered "shorted out."

EXAMPLE:

$R_1 = 10$ $R_4 = 40$

$R_2 = 20$ $R_5 = 50$

$R_3 = 30$

FIG. 27

14786

A. First we short out one source, arbitrarily picking "B." Now we have a simple combination circuit.

FIG. 28

B. Calculate R_1, and I R_1 through I R_5. Label your answers I_{1a} through I_{5a}.

C. Replace the "B" source and short out the "A" source.

FIG. 29

14787

D. Calculate R_T and I R_1 through I R_5. Label the answers I_{1b} through I_{5b}.

E. Redraw the combined circuit, labeling "A" current "Diamond" and "B" current "Arrows," as in Figure 30.

FIG. 30

F. Enter the algebraic sums, using the subtractive method, and showing the direction with an arrow, as in Figure 31.

FIG. 31

14788

G. Using Ohm's Law, we find E R_3 to be 8.49v, in the direction shown by the arrow. All other values can be easily found.

H. Current sources would be worked out similarly, using an open circuit instead of a short.

EXAMPLE:

FIG. 32

Open one source and calculate the needed values, as in Figure 33.

FIG. 33

14789

Open the other source and calculate the needed values, as in Figure 34.

FIG. 34

Combine algebraically as in Figure 35.

FIG. 35

I. Ohm's Law will now resolve all voltages and powers.

14790

PROCEDURE

1. Construct the following circuit on the patch panel.

FIG. 36

2. Connect source "A" to CT and Tap. Adjust for 20v output.
3. Connect source "B" to BT and B-. Set to 25v output.
4. Calculate and then measure all voltages and currents, noting all significant differences.
5. Construct the following circuit on the patch panel.

FIG. 37

14791

6. Calculate, then measure all currents and voltages. (Indicate direction.)
7. If R_3 were replaced by a lamp with an internal resistance of 2.2K, the lamp would develop _____ watts.

CONCLUSIONS

Many circuits use more than one source of energy. Step analysis reduces them to relatively simple circuits. You must know and understand the two major methods used -- closed and open sources.

EXPERIMENT #17 THEVENIN'S THEOREM

OBJECTIVE

To simplify complex circuits by reducing them to simple circuits where Ohm's Law may be used.

MATERIAL REQUIRED

Patching panel
VOM and VTVM
Power supply
Accessory kit

INTRODUCTION

Thevenin's Theorem states: Any two-terminal circuit can be replaced by a simple series circuit consisting of an equivalent voltage source and resistance where:

A. The equivalent source is the voltage that would be present at the load terminals with the load removed.
B. The equivalent series resistance is the resistance that would be measured at the load terminal with the source replaced by its internal resistance and the load removed.

The theorem takes into consideration that the source voltage must be held constant.

EXAMPLE:

To find I R_3 and E R_3:

R_1 = 10K R_2 = 20K R_3 = 20K (LOAD)

FIG. 38

14793

213 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Remove the load. Calculate E_{TH} (equivalent voltage) at the load point (67v)

FIG. 39

Replace the source by a short (assuming source resistance is low).

FIG. 40

14794

Looking back from the load, R_1 and R_2 are in parallel. Lump and call them R_{TH}.

FIG. 41

The circuit can now be solved by Ohm's Law. The I_T in this circuit is 2.5 ma; hence the IR_3 is also 2.5 ma because of the series-circuit arrangement. The ER_3 is 50 volts. This is a very simple circuit, but the principle may be applied to the most complex circuit. The circuit often can be resolved by visual inspection.

14795

EXAMPLE #2

It is not easy to find I R_6 or E R_6 by visual inspection. If we apply the theorem to the circuit (twice) we can simplify it.

FIG. 42

Regard everything beyond R_3 as the load. This places R4, R5 and R6 as the load. It also places R_1, R_2 and R_3 in the source circuit.

FIG. 43

14795

14796

The circuit has the load removed. Determine E_{TH} by looking back from the load terminals. Notice that R_3 has no voltage developed, as there is no current-path through it. The source voltage divides equally between R_1 and R_2. This means that E_{TH} = 40v. To find R_{TH}, replace the 80v battery with a short, placing R_1 and R_2 in parallel but still in series with R_3. R_{TH} = 10 ohms: R_1 and R_2 in parallel produce an equivalent 5 ohms, which is in series with R_3, a 5-ohm resistance, for a total of 10 ohms.

FIG. 44

Introduce the load circuit, designating R_6 as the load, and remove it again to determine E_{TH} and R_{TH}. Calculate E_{TH} = 20v and R_{TH} = 10 ohms.

FIG. 45

14797

Reconnecting the circuit, we find the simplified circuit, the equivalent circuit of the 6 original resistors, much easier to analyze.

PROCEDURE

1. Construct the following circuit.

R_1 = 15K R_3 = 22K

R_2 = 10K R_4 = 18K

FIG. 46

2. Adjust C+ to 15 volts dc. Measure E R_1 to ER_4 and I R_1 to I R_4.
3. Consider R_4 to be the load resistance to be found by calculation.
4. Calculate E R_4 and I R_4. Compare the calculation with the measured values as per step #2.
5. Construct the following circuit.

14798

R_1 = 47K R_4 = 56K

R_2 = 22K R_5 = 5.6K

R_3 = 18K R_6 = 15K

FIG. 47

6. Consider R_6 as the load, and calculate the values, using Thevenin's Theorem; then measure I R_6 and E R_6. Compare all results.

CONCLUSIONS

Beginning with a very complex circuit, we can make use of several repetitions of Thevenin's Theorem to calculate a simple equivalent circuit, readily solved. The theorem is widely used in research to analyze semi-conductor circuitry.

QUIZ

1. In which of the circuits discussed or calculated in this experiment is maximum power dissipated by the designated load? Explain your answer.
2. What effect do the component values have on the value of Thevenin's equivalent resistance?
3. Using Ohm's Law, calculate any of the circuits constructed. Compare this solution with the Theorem method. List any advantages noted when using Thevenin's Theorem.

14799

00841

EXPERIMENT #18 WYE-DELTA NETWORK

OBJECTIVE

To learn to reduce complex circuits, which often cannot be reduced by Ohms Law.

MATERIAL REQUIRED

Breadboard
VOM
Power Supply
Accessory Kit

INTRODUCTION

The Delta and Wye are types of circuit connections.

FIG. 48

An example of a Delta-Wye conversion

14800

FIG. 49

The circuit in Figure 49 contains a bridge network across a source. If R_T were to be determined by Ohm's Law, it would be a difficult task. Between points A, B, and C a delta network is formed. If the network were replaced by a Wye at these points, as in Figure 50, Ohm's Law could resolve the circuit.

FIG. 50

Figure 50 shows the delta replaced by a wye with

14801

ILLUSTRATIONS SHOWING THE EFFECT OF LINE ON FIGURE TYPES

Optical illusions may be created for various figure types by using lines such as horizontal, vertical, curved, and diagonal. Vertical lines give the illusion of height; panels, of width; and tapered panels, of slenderness. The use of the vertical line is shown below.

Medium

Short and Heavy

1477

R_6 through R_8 replacing R_1 through R_3. Since the circuits would be electrically identical, the voltage appearing across R_3 in the original circuit would appear between B and C, or across R_7 and R_8 in Figure 50.

This is one method used to find the equivalent values of resistance, converting from delta to wye or the reverse.

FIG. 51

The circuit could be converted to a wye with the substitution of R_4 through R_6, thereby simplifying the network.

The question arises: If the delta values of resistance are known what would be the values of the wye in order to <u>BE</u> equivalent? The conversion tables:

$$R_4 = \frac{R_1 \; R_2}{R_1 + R_2 + R_3}$$

$$R_5 = \frac{R_1 \; R_3}{R_1 + R_2 + R_3}$$

$$R_6 = \frac{R_2 \; R_3}{R_1 + R_2 + R_3}$$

In a similar manner, a wye-to-delta conversion:

$$R_1 = \frac{R_4 \; R_5 + R_4 \; R_6 + R_5 \; R_6}{R_6}$$

10841

14802

$$R_2 = \frac{R_4 R_5 + R_4 R_6 + R_5 R_6}{R_5}$$

$$R_3 = \frac{R_4 R_5 + R_4 R_6 + R_5 R_6}{R_4}$$

More elaboration on bridge circuits will follow in Experiment #19.

PROCEDURE

1. Construct the circuit below on your patch panel.

FIG. 52

2. Measure R between points.

   A to B = _____
   A to C = _____
   B to C = _____

3. Connect Ct to point A, tap to B, and adjust for 10 volts dc.
4. Measure and record the voltage between A - C and B - C.
5. Move the power supply to point C (Ct) and -B (tap).
6. Measure and record the voltage from point A - B and A - C.
7. Convert the delta network to a wye.
8. Select 3 resistors that are close to the calculated values in step 7. Wire on the patch panel.
9. Measure and record the resistance between A - B, A - C, and B - C on the wye network. How do these resistances compare to points A to B, A to C, and B to C in the delta arrangement in step 2?
10. Connect a 10v supply between points A and B .

14803

11. Measure and record the voltage between points A - C and B - C. Compare these voltages to previous readings of the delta network.
12. Connect a 10v supply between A - C on the wye patch. Measure and record the voltage between points A - B and B - C.
13. Connect the 10v supply between B - C on the wye patch. Measure the voltages between A - B and A - C.
14. Construct the following circuit.

FIG 53

15. Measure R_T between points A - B and C - D.
16. Convert the delta (top section) to wye, calculating the R_T. Compare step 15 to 16.
17. Measure the resistance between points C and D.
18. Change R_2 to 160 ohms. Measure the resistance between points C and D.
19. Now change R_2 to 10 ohms. Measure resistance between points C and D.
20. Compare steps 17 through 19.

CONCLUSION

After learning how to convert delta circuits to wye circuits, the solution of complex networks can be obtained using Ohm's Law.

14804

EXPERIMENT #19 DC BRIDGE CIRCUITS

OBJECTIVES

To gain a working knowledge of bridge circuits.

To construct an experimental voltage or resistance bridge used in testing precision measurements.

MATERIAL REQUIRED

Breadboard
VOM (2 Reqd.)
Accessory kit
4 #6 dry cells (Because of the current regulation required, batteries are used as the power supply in this experiment.)

INTRODUCTION

One of the most widely used instruments in quality-control testing is called the resistance bridge. This bridge is used in very low tolerance circuits where .1 ohm is critical. A dc bridge circuit is shown below in Figure 54.

FIG 54

14805

14805

This is more commonly drawn as in Figure 55.

FIG. 55

It is worth noting that $R_1 - R_2$ and $R_3 - R_4$ are each in series across E_{bb} and act as voltage dividers. Point 1 voltage is determined by the $R_1 - R_2$ resistance ratio. Conversely, point 2 value is determined by $R_3 - R_4$ resistance relationship. A meter inserted between points 1 and 2 (M_1) would indicate the emf existing between those points. For example if R_2 and R_4 are in the same proportion as R_1 and R_3, M_1 would read zero, as no current would flow through the meter movement. Hence the name "balanced bridge". This type of bridge can be used to measure either voltage or resistance. For example, if R_4 were unknown and R_3 were variable (a calibration resistor), varying R_3 until M_1 indicated zero would indicate that I R_4 and I R_3 were in the same proportion as I R_2 and I R_1. R branch 1 would equal R branch 2. By reading the calibration resistor (R_3), R_4 value could be readily calculated.

From the ratio $\frac{R_1}{R_3} = \frac{R_2}{R_4}$, we know that $R_1 R_4 = R_2 R_3$. We can solve this equation for any of the resistances R_1 through R_4.

$$R_4 = \frac{R_2 R_3}{R_1}$$

$$R_3 = \frac{R_1 R_4}{R_2}$$

$$R_2 = \frac{R_1 R_4}{R_3}$$

$$R_1 = \frac{R_2 R_3}{R_4}$$

14806

14806

Normally R_1 and R_3 are fixed precision resistors with predetermined ratios. The value of R_2 is read on a calibrated dial and multiplied by a simple ratio R_3/R_1 which may be 1:10, 1:1, 10:1, etc.

If R_1 and R_3 are 1:1, R_2 and R_4 (the unknown) will also be 1:1. Normally, a special meter called a center-zero meter is used. The pointer has the ability to move either left or right from a static position. Normal meters usually have their static position on the left side or the right side(ohmmeter). This center zero protects the meter, since the current may flow in either direction from the zero position. A VOM meter movement can usually be adjusted "off" normal zero by moving the mechanical zero-adjustment screw which sets the pointer off the left-or right-hand edge. This can be set to some even number of the scale, which would then equal static zero. The setting can be 10, 20, or 50, etc. with the range switch set to a high range. The range is then reduced until it accommodates the maximum swing.

PROCEDURE

1. Obtain a piece of cardboard 2" x 2". Set its extremes on the potentiometer as shown and mark in percentages as shown in Figure 56.

FIG. 56

2. Remove the knob and nut from the potentiometer and mount the cardboard under the nut. Assemble, making sure that the knob extremes are at 0 and 100.
3. Construct the following circuit. (R_3 is the potentiometer.)

60841

14807

R_3 = 500 OHM

CALIBRATION POT

FIG. 57

4. Connect an ohmmeter to terminals X. Turn R_3's knob so that the pointer reads exactly at zero (as per your drawing on the cardboard). Read the ohmmeter and record the obtained value in the chart, Figure 58. Set the potentiometer for each of the scale points listed on the calibration chart and record the resistance readings for each setting.

SCALE	RESISTANCE	SCALE	RESISTANCE
0		55	
5			
10			
50		100	

FIG 58

5. Using the data in the chart, Figure 58, plot a resistance curve for your potentiometer. Use Figure 59. This curve will show the resistance of the 500-ohm potentiometer for any setting of the dial.

14808

FIG 59

14809

14810

6. Construct the following circuit:

FIG. 60

*Read the introduction before proceeding.

7. Assume R_x is an unknown value. Arbitrarily place a 160 ohm - 1 W resistor at R_x. This resistor has 5% tolerance. It can read between 152 and 168 ohms with the 5% tolerance range. The bridge will read with a tolerance that is dependent on the tolerances of all its circuit components.
8. M_1 (off; mechanical zero) should be placed on approximately the 100 ma scale. Insert M_1 into the circuit. Using the graphed calibration chart, set R_c to 160 ohms.
9. Close L_1 and note the M_1's pointer movement. If there is none, the bridge is balanced, proving that the "unknown" resistor really is 160 ohms. If there is some movement, adjust R_c until the pointer returns to the zero.
10. Lower the range switch to provide a more sensitive reading. Adjust R_c until the pointer indicates zero. Record all pertinent information.

QUIZ

1. If a potentiometer is to be used in a bridge, why must the resistance be accurately known for each setting?
2. Is the resistance of R_c linear? Would it be desirable in this application?
3. Does the accuracy of R_1 and R_2 affect the unknown resistance's theoretical value?

14810

EXPERIMENT #20 INDUCTANCE (Self and Mutual)

OBJECTIVES

To observe the effects of self and mutual inductance.

MATERIAL REQUIRED

Power Supply
Breadboard
Accessory Kit
VOM and VTVM

INTRODUCTION

Inductance is the property of a component which tends to keep a changing current constant. An inductance is determined by the equation:

$$L = \frac{R^2 N^2}{9R + 10I} \quad \text{(Air core-single layer)}$$

Where
L = inductance in μ-henries
R = Radius in inches
N = Number of turns
I = Length of coil in inches

A henry is equal to a change in current of one ampere per second, inducing an emf of one volt.

When two coils are positioned where the flux from one coil cuts turns of another coil, a voltage is developed in the second coil. (secondary). This is called transformer action. The energy in the second coil is dependant upon a factor called the coefficient of coupling (K).

The second coil can then draw current, due to the induced emf, and may either aid (+) or oppose (-) the originating source. This additional inductance developed by the originating coil (primary) is called mutual inductance (M). $M = K\sqrt{L_1 L_2}$ where the coils are connected in series, with mutual inductance. The total series inductance is:

$$L_T = L_1 + L_2 \pm 2M$$

+2M if the coils' flux fields add
-2M if fields oppose

14811

14811

EFFECT OF LINE ON FIGURE TYPES

Tall and Thin

Short and Heavy

1478

The formula for parallel inductance is:

For Aiding Fields $\frac{1}{L} = \frac{1}{L_1+M} + \frac{1}{L_2+M}$

For Opposing Fields $\frac{1}{L} = \frac{1}{L_1-M} + \frac{1}{L_2-M}$

PROCEDURE

1. Set up the circuit shown below:

FIG. 61

2. Set B+ to 80 volts dc. Keep the coils close to each other.
3. Depress S_1 and note the results on NE_2 and the 7-watt lamp.
4. Release S_1 and note the momentary flash of NE_2(counter-emf of T_1) and the gradual diminishing of the lamp.
5. Short out points B and E. Depress S_1 and note the effect on NE_2 and the lamp.
6. Open S_1 and note the effect of "No" inductance in the circuit and the action of the bulbs.
7. Compare step 3 and step 5, inductance in and out of the circuit.
8. Wire the following circuit:

14811

14812

FIG. 62

9. Position $coil_1$ and $coil_2$ as far apart as possible.
10. Adjust C+ (VOM) for 2 volts dc.
11. Adjust the VTVM for a zero-center scale on the 5-volt dc scale.
12. Close S_1 and note the effect on the VTVM.
13. Open S_1, slide coils 1 and 2 together. Now repeat steps 10 to 12.
14. Move the coils apart, one quarter inch at a time, repeating step #12 each time.

CONCLUSIONS

Self inductance is the result of energy storage and release into the circuit, whenever current changes. It is possible to transfer some of this stored energy to another coil brought in proximity to the original coil.

QUIZ

1. List the factors that contribute to an inductor's ability to store energy.
2. Does an inductor oppose current? How can you prove this?
3. Why does the secondary voltage decrease if coils 1 and 2 are pushed apart?
4. How does an iron core contribute to the amount of mutual inductance or transfer of energy?
5. Is it possible, with 2 volts applied to $coil_1$, to have much more than 2 volts induced into $coil_2$? Why?
6. What is unity coupling and how can it be achieved?

14813

14881

EXPERIMENT #21

INTRODUCTION TO CAPACITORS AND TIME CONSTANT

OBJECTIVE

To examine a typical capacitor application and observe the effect of capacitors connected in series and parallel.

MATERIAL REQUIRED

Power Supply
Breadboard
VTVM
Accessory Kit

INTRODUCTION

Types and Construction

Aside from the resistor, a capacitor is the most frequently used component in any circuit. Because of the capacitor's constant use, it is necessary for an electronics technician to become familiar with many types of capacitors.

It can be said that a capacitor is constructed of two conductors, with a dielectric or insulating material between them. If a battery were connected across the plates of a capacitor, it would place a negative charge on one of the plates and a positive charge on the other plate. This means that there is an emf across the capacitor. After disconnecting the battery the capacitor will remain charged. If a wire were used to connect the two plates, the excess of electrons on the negatively charged plate would flow toward the positively charged plate because of its deficiency of electrons. Thus current would flow through the wire.

It is necessary to understand the various types of capacitors, their special uses, their special construction, and polarity observations. The unit of measuring capacity is related to the physical size of a capacitor.

Paper Capacitors

The construction of a paper capacitor is relatively simple. It is comprised of two layers of metal foil sandwiched between the layers of waxed paper alternately placed, as illustrated in Figure 63A. The plates are the foil, which is capable of holding the charge, and the waxed paper acts as the insulating material (dielectric) between the plates. In some cases the whole capacitor is impregnated, or soaked, with oil.

61841

14814

Soaking the capacitor with oil has two advantages: it enables the capacitor to have a higher breakdown voltage and also protects it against corrosion. A paper capacitor has no polarity as far as negative and positive terminals are concerned. However, its construction (Figure 63A) makes it necessary that one plate cover or engulf the other plate. This foil plate is referred to as the outer foil. The lead coming from the outer foil is usually identified by a ring or dot at that end of the capacitor or a ball of solder at the base of the lead. Figure 63B illustrates the three common methods of identification. One purpose of identifying the outer foil lead is as follows:

> If a blocking capacitor in the grid circuit is connected to the grid by the outer foil lead, then the whole outer foil will act as an antenna. This antenna will pick up and pass on any interference to the tube.

FIG 63

14815

Electrolytic Capacitors

Electrolytic capacitors work on the same principle as a paper capacitor. The major difference is that an electrolytic capacitor has a definite prearranged polarity. It is constructed so that only one side, or plate, is capable of being charged negatively. This is due to the type of dielectric used between the plates. This condition is accomplished by having a borax solution between the plates. When the capacitor is first assembled, a slight dc voltage is applied across the plates and is gradually increased. At the end of this process an aluminum oxide has formed on one of the plates, and this comprises the dielectric. Thus it can be seen that if, when using the capacitor in a circuit, the polarity of the applied voltage was connected backward, the oxide coating would break down and the dielectric would be destroyed. CAUTION: ALWAYS OBSERVE THE POLARITY OF AN ELECTROLYTIC CAPACITOR. Also, due to this type of dielectric, an electrolytic capacitor has a certain amount of leakage between the plates. This leakage is present in all electrolytic capacitors. The aluminum oxide dielectric is not a good insulator and allows a slight current flow between the plates. However, this disadvantage is compensated for by the fact that an electrolytic capacitor has much more capacity than other capacitors of like physical size. The resistance for an electrolytic capacitor rated at 200 volts should not be under 200K, and a capacitor rated at 450 volts should not have a resistance of less than 1 M.

Ceramic and Mica Capacitors:

CUTAWAY VIEW OF A MICA CAPACITOR

FIG 64

14816

A problem arises when a capacitor is used in a high-frequency circuit. A paper or an electrolytic capacitor absorbs a portion of the charge during the positive half of the ac cycle and does not fully discharge during the negative half of the cycle. In other words, if you were to charge a paper capacitor and then discharge it, a few minutes later you could discharge it again. This is caused by the dielectric's retaining some of the charge and not giving it up. The ceramic and mica capacitors were developed to overcome this problem. These capacitors have the ability to quickly and completely discharge, enabling them to follow a very high frequency. They have this special ability because they use a ceramic or mica dielectric, which absorbs very little of the charge applied to the capacitor. Figures 64 and 65 illustrate the construction of a mica and ceramic capacitor.

OPEN VIEW OF A DISC-TYPE CERAMIC CAPACITOR

FIG 65A

CUTAWAY VIEW OF A TUBULAR-TYPE CERAMIC CAPACITOR

FIG 65 B

Checking a capacitor may appear to be a simple and unimportant job. However, experience will show that in order to find the trouble in a piece of electronic equipment quickly and accurately, you must be able to check a capacitor with speed and precision. A technician should develop his methods of checking capacitors so that when troubleshooting a particular circuit he will definitely know whether a capacitor is good or bad.

Capacitors Connected in Series and Parallel

When two or more capacitors are series connected, the total capacitance (C_T), always has a value smaller than the smallest capacitance in the series string. Parallel-connected capacitors add

14817

directly. This is just the reverse of resistors connected together. The formulas for calculating combined capacitance, then, are the resistance formulas with the correct symbols and applications.

Series connections $C_T = \frac{C_1 C_2}{C_1 + C_2}$ or $C_T = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}}$, etc.

Parallel connections $C_T = C_1 + C_2 + \ldots\ldots\ldots\ldots C_n$

Two other formulas are used in capacitive circuits:

$$C = \frac{Q}{E}$$

Where C = capacitance in farads, Q is the ratio of charge, and E is the emf.

The capacitance of a parallel-plate capacitance consisting of two plates of surface area A each (in cm^2) and separated by a distance d (cm), is:

$$C = \frac{KA}{4\pi d}$$

where K is the dielectric constant of the material between the plates and C is the capacitance in farads.

PROCEDURE

1. Construct the following circuit:

FIG. 66

14818

2. Adjust T-C+ to 40 volts
3. Connect a VTVM from points A to B, using the 0 to 50 volts dc range.
4. Close S_1, noting the rate at which C_1 charges. Calculate the time constant from the following equation:

$$T_C = RC$$

where T = Time in seconds
R = Resistance in ohms
C = Capacitance in farads

Multiply T_C x 5 for 100% charge.

5. After experimenting with the charge time, open S_1 and short out A to C. Record the discharge time (when VTVM reads 0 volts).
6. Place a second 1 µf capacitor between A and B.
7. Repeat steps 4 and 5.
8. Replace R_1 with a 4.7 M ohm resistor. Repeat steps 4 and 5.
9. Add .1 µf capacitor in series with C_1.
10. Repeat steps #2 through #5.
11. Record all pertinent data.

CONCLUSIONS

Five RC time constants is the charge or discharge time of capacitors regardless of the size of R or C. A thorough understanding of T=RC is a prerequisite for workers in the electronics field.

QUIZ

1. What percentage does a capacitor charge to in 1 T_C, 2, 3, 4 and 5 + C?
2. What is the percent of discharge in each of the above?
3. How do capacitors in series and parallel affect the time constant?
4. How does Kirchhoff's Law apply to this circuit consisting of R and C? Expand upon your explanation.

ABSTRACT - Prepared by educators in Warren County Schools of New Jersey in cooperation with the Vocational-Technical Laboratory of Rutgers University, this is the second of two laboratory manuals for teacher and student use in teaching the fundamentals of electronics. Contents are designed to challenge prospective electronics technicians through problem-solving techniques concerning A-C circuits. The 16 experiments, for use with a basic electronics or electricity textbook, include objectives, introduction, material or equipment required, procedure, conclusions, and questions. A list of electronic symbols is appended. Part one is available as VT 012 900, also in this issue. (GEB)

FOREWORD

This Laboratory Manual is written in an attempt to challenge the intellect of the prospective electronics technician. This is accomplished by using the problem-solving technique. The ability to solve problems is a vital prerequisite to the fulfillment of the job classification.

This Laboratory Manual was written to be used in conjunction with a basic electricity or electronics textbook.

Some of the experiments include introductions, as some textbooks do not relate the material content of the theory to a working (laboratory) knowledge of experimentation.

The experiments are arranged in a spiraling order. This provides an increasing level of skill and knowledge each time the general topic is presented.

EXPERIMENT #1

INTRODUCTION AND APPLICATION OF THE OSCILLOSCOPE

OBJECTIVE

To develop the knowledge and skill required in using an oscilloscope.

INTRODUCTION

Model 460
DC - Wide Band
Oscilloscope

Cathode-Ray Tube

Type	5UP1
Accelerating Potential	1200 volts (2nd anode with respect to cathode)
Illuminated Scale	Engraved, illuminated plexiglass scale over face of tube; dimmer control provided on front panel.
Filter Bezel	Special green acetate matches screen phosphor. Standard 5" CET bezel fits standard photographic equipment.

Vertical Channel

Sensitivity (at full gain)	25 millivolts rms/inch
Undistorted Deflection	greater than 4 inches
Frequency Response (sinusoidal)	
Direct Coupling	Flat (+1, -3 dB) from dc to 4.5 mc
[redacted]pacitive Coupling	Flat (+1, -3 dB) from 1 cps to 4.5 mc

[redacted]

Transient Response	
Rise time	0.06 microseconds max.
Overshoot	8% max.
Input voltage (maximum)	
Unbalanced (either coupling)	600 volts (dc plus peak ac)
Balanced	1 volt p-p
Input Coupling	Capacitive or direct
Attentuation (switch-type)	By factors of 1, 10, 100, and 1000± 5% as selected by VERT. ATTENUATOR selector; frequency compensated so that there is no visible change in waveshape at any attenuator position.
Input Impedance	
Single-ended (unbalanced)	3 megs shunted by 35 mmf
Balanced	6 megs shunted by 20 mmf
Positioning	± 2 inches; permits centering on screen of any portion of trace expanded vertically to 4" peak-to-peak.

Horizontal Channel

Sensitivity	0.6 rms volts per inch
Frequency Response	Flat (± 1dB) 1 cps to 400 kc
Input Impedance	Approximately 5 megs shunted by 35 mmf (at 1 kc).
Expansion	To 2 times full-screen diameter without distortion.
Positioning	So any portion of expanded trace may be examined on screen.
Horizontal Inputs	Linear time base with choice of synchronization described below, phase-controlled 60 cps input, or external input.

Linear Time-Base Generator (Recurrent)

Frequency Range	10 to 100,000 cps sawtooth in 4 ranges plus EXTERNAL CAPACITOR position. A sweep range down to 1 cps may be obtained by connecting an appropriate capacitor between EXT. CAP. terminal and ground. Special TV-V and TV-H positions provide 30 cps and 7875 cps sweeps respectively for convenience in TV servicing.
Synchronization	"+" internal, "-" internal, 60 cps (phase controlled), or external.

Intensity Modulation Circuit (Z Axis)

Input Impedance	Approximately 0.1 meg at medium intensity setting.
Sensitivity	Approximately 3 volts rms for blanking the beam.
Polarity	Beam intensity increased on positive excursion of signal.

Calibration Voltage

Availability	Switched to input of vertical amplifier by setting VERT. ATTENUATOR selector to CAL.
Waveshape	Sinusoidal
Frequency	60 cps
Amplitude	400 millivolts peak-to-peak
Accuracy	± 5% factory-adjusted; add accuracy of meter used for initial adjustment in kit instruments.
Useful range	With calibrated graph screen and calibrated vertical attenuator provided, permits voltage measurement over range of 100,000 to 1.

Sawtooth Output

Availability	Front-panel terminal
Amplitude	15 volts peak-to-peak max. (Varies with hor. gain control).
Polarity	Positive
Frequency	Same as linear time-base generator
Impedance	Approximately 300 ohms.

60 CPS Output

Availability	Front-panel terminal
Amplitude	3 volts rms.

General

Sync Voltage	Amplifier limiter circuit provides automatic control; no sync voltage adjustment required.
Phasing Control	Provides fully controlled phase shift for 60 cps sweep application.
Power Supplies	One high voltage, one low voltage; both transformer rectifier type with RC filter systems.

Tube Complement	2-6AU8, 2-6CB6, 2-6J6, 1-12AU7, 1-6AX5, 1-1V2.

Physical Specifications

Shipping Weight	30 lbs.
Overall Dimensions	14 3/4" high, 8 1/2" wide, 16 1/2" deep
Cabinet	Steel; grey wrinkle finish
Panel	Heavy gauge aluminum; brushed satin finish; etched rub-proof legends.

Cop 1482[illegible]

MATERIAL REQUIRED

6" oscilloscope
Audio Signal generator

PROCEDURE

Follow the succeeding instructions with the use of an oscilloscope, preferably an EICO 460.

FUNCTIONS OF CONTROLS AND TERMINALS

The oscilloscope controls and terminals are easy to use once their functions are understood.

If the controls are divided into specific groups, for purposes of explanation, it will be easier to understand and keep in mind just what these functions are.

The INTENSITY and FOCUS knobs together control the appearance of the trace. The INTENSITY knob controls the brightness of the trace and the FOCUS knob controls the sharpness or definition of the trace on the scope screen. Proper adjustment of these controls should give a trace formed from a thin bright line or an undeflected spot of light that is tiny, round, and bright. (1)* These controls interact to an extent; that is, adjustment of the FOCUS knob is usually necessary when the setting of the INTENSITY knob is changed. (2)

The V-POS (Vertical-Position) and H-POS (Horizontal-Position) knobs control the location of the trace on the screen. Turning the H-POS knob shifts the trace left or right (3) and turning the V-POS knob moves the trace up or down. (4) (5)

The VERTICAL ATTENUATOR provides a choice of no attenuation or three decade steps of frequency-compensated attenuation (6) of the input voltage fed to the vertical amplifier. Each attenuation is obtainable with either direct coupling provided to the vertical amplifier (positions under the dc arc on the dial), or capacitive coupling to the vertical amplifier (positions under the ac arc on the dial). At either "1" position, the amplitude of the signal voltage is unchanged (no attenuation). At either of the "10", "100", "1000" positions, the amplitude is attenuated by a ratio of 10:1, 100:1, and 1000:1 respectively. At the CALibrator position, a 0.4 volt peak-to-peak sine wave at power-line frequency is fed to the vertical amplifier. (7) (8)

The VERTICAL GAIN control allows continuous adjustment of the vertical amplifier gain. (9) It is used with the VERT. ATTENUATOR selector to adjust trace height to the desired value.

The HOR. SELECTOR combines the functions of sync selector for the internal sweep and input selector for the horizontal amplifier. At any of the four most counterclockwise positions (under the SYNC-SWEEP arc on dial) the internal linear sweep is fed to the horizontal amplifier. These four positions permit selection of sync voltages for the sweep oscillator. At the "+" and "-" positions, the synchronizing voltage is taken internally from the vertical amplifier. At "-", the sweep trace flyback starts during the negative-going excursion of the voltage applied to the vertical amplifier. (10) At the "EXT." position, an external synchronizing voltage applied between the H-INPUT/EXT. SYNC.

* Notes begin on page 101.

terminal and ground is fed to the sweep oscillator. (11) At the 60 cps position, an ac signal of power-line frequency is taken from the power supply and applied to the sweep oscillator to sync it at line frequency. The PHASING control is effective in the 60 cps SYNC position and permits phase adjustment of the 60 cps sync voltage to shift the starting point of the waveform display to any desired point on the waveform. (12)

At either of the two most clockwise positions of the HOR. SELECTOR (under HOR arc on dial), the sweep oscillator is disabled. At the 60 cps HOR. position, an ac signal of power-line frequency is taken from the power supply and applied to the input of the horizontal amplifier. The PHASE knob controls the phase shift of the line frequency voltage used for sinusoidal sweep. (13) At the EXT. HOR. position, an external signal voltage fed between the H-INPUT/EXT. SYNC. terminal and ground is applied to the input of the horizontal amplifier. The HOR-GAIN control is effective in both the 60 cps HOR. and EXT. HOR. positions.

The SWEEP FREQUENCY band selector selects the frequency band over which the SWEEP VERNIER (fine sweep-frequency control) can be varied for frequency adjustment of the internal linear sweep. The numbers on either side of the markers are the upper and lower limits of the band (approximately). The four positions, reading from left to right are 10-100 cps, 100 cps-1 kc, 1-10 kc, 10-100 kc. The EXT. CAP position is used when it is desired to obtain a linear sweep below 10 cps down to approximately 1 cps. A 0.5 mf external capacitor (rated at least 200 wvdc) must be connected between the EXT. CAP and SAWTOOTH terminals for sweeps down to 1 cps. (14)

The V & H positions (under the TV arc on the dial) are designed to eliminate the need for repeated readjustment of the SWEEP VERNIER in TV work. If, with the SWEEP SELECTOR set at the TV-V position, the SWEEP VERNIER is set to display two full cycles of a 60 cps signal to obtain a sweep frequency of 30 cps, turning the SWEEP SELECTOR to TV-H will result in a sweep frequency of 7875 cps without readjustment of the SWEEP VERNIER. (15)

The V-INPUT terminals provide for connection of external signals to the vertical amplifier. An external jumper must always be used to short the lower of the two terminals to ground for conventional single-ended input. Remove the jumper for balanced input. (No attenuation may be derived from the vertical step attenuator on balanced input because this attenuator affects only input signals fed to the upper of the two V-INPUT terminals.) See NOTES ON CONTROLS & TERMINALS for use of balanced input. (16)

An external voltage for purpose of intensity (Z-AXIS) modulation may be applied between the Z-AXIS binding post and ground. Never apply an intensity modulating signal that is large enough to swing the grid of the cathode ray tube positive, or the life of the tube may be greatly shortened. Positive grid swing is indicated by noticeable defocusing of the trace during the positive phase of the intensity modulating signal.

1480

A test voltage of power-line frequency is available between the 60 cps terminal and ground. The amplitude of this voltage varies with load.

A sawtooth voltage from the output of the sweep circuit oscillator is available between the SAWTOOTH terminal and ground. The frequency of the sawtooth is, of course, variable by the SWEEP SELECTOR and SWEEP VERNIER controls. The amplitude is variable by the HOR-GAIN control.

The AC POWER switch is ganged with a dimmer control for the lamp which edge-lights the plexiglass scale.

NOTES ON CONTROLS AND TERMINALS

1. Proper trace definition will be obtained only if the astigmatism control is correctly adjusted (See Maintenance) and the scope is not operated in strong fields such as are found near transformers, transmitters, and power generating equipment, etc., which may distort the electron beam that produces the trace.

2. A sharply focused short line or a small spot of high intensity should not be permitted to remain stationary on the screen for any considerable length of time (more than ½ minute) or the screen will be burned. A trace of excessively high intensity will burn the screen in 3 to 5 minutes. These burned portions of the screen will no longer fluoresce and are useless for observation. If it is required to have a fixed trace on the screen for a long period, reduce the intensity of the trace to a minimum.

3. A trace can be expanded vertically beyond full-screen width without distortion. This is particularly important in dealing with sweep waveforms. The range of horizontal positioning is several times full screen to permit examination of any part of the expanded trace.

4. A trace can not be expanded vertically beyond full-screen width without distortion. Vertical positioning beyond the ±2 inches obtainable is, however, useful, since this range of positioning will permit bringing the top or bottom of any trace expanded vertically to full-screen width into the central region of the screen where screen curvature will not cause blurring of these portions of the trace.

5. When the VERT.-ATTENUATOR control is set at one of the positions under the DC (direct-coupled) arc on the dial, the dc component of any signal fed to the vertical amplifier will be amplified along with the ac component of the signal and be reflected on the screen by a proportional vertical movement of the trace. The direction of the trace movement depends on the polarity of the dc component. Therefore, when going from observation of a pure ac wave to one containing dc or vice versa, it may be necessary to use the V-POS control to bring the trace back to center screen. The dc component of a signal has no effect at the AC (capacitive-coupled) positions of the VERT.-ATTENUATOR.

6. Trimmer capacitors C2, C3, and C4 are used for compensating the vertical step attenuator at the 1000, 100, and 10 positions respectively. See MAINTENANCE section for procedure.

7. See OPERATION section for use of CALibration position.

8. Potentiometer R6 is used to set the peak-to-peak value of the calibrating voltage to the prescribed value. See MAINTENANCE section for procedure.

9. Potentiometer R16 is the dc balance adjustment. When R16 is adjusted properly, there will be no shifting up or down of the trace on turning the VERT. GAIN control from minimum to maximum with no input signal to the vertical amplifier.

10. The +(INT.) and -(INT.) positions allow the synchronization of any type of non-sinusoidal waveform.

11. The EXT. sync. position is for use with generators or other devices which have sync. outputs.

12. The PHASING control action in the "60 CPS" HOR. position permits use of sweep generators that do not have phase-controlled 60 cps sinusoidal sweep outputs or dispensing with connections to such outputs when they are available.

14. Large-valued capacitors will give lower sweep frequencies (approximately 1 mf for a sweep as low as 0.5 cps). However, good results below a few cps can not be assured.

15. Trimmer C22 must be adjusted initially in kit instruments to display two full cycles of a 15750 cps signal at the TV-H position after the SWEEP VERNIER has been set to display two full cycles of a 60 cps signal at the TV-V position. See MAINTENANCE section.

16. Use of the balanced input to the vertical amplifier makes it possible to reject any common-made signal (in-phase signal applied to both inputs) while at the same time passing and amplifying the balanced input signal. In this way, noise pickup in the test leads or in the equipment under test can be greatly reduced. Balanced input is obtained by removing the jumper between the lower of the two V-INPUT terminals and ground, setting the VERT. ATTENUATOR at the "1" position under the DC arc and feeding the signal to be observed between the two upper V-INPUT terminals. Use of the balanced input is limited by the fact that no step attenuation is possible because there is only one step attenuator in the instrument and therefore only one of the inputs could be attenuated. Therefore, with balanced input, full-scope sensitivity is obtained and the maximum amplitude of signal that can be observed without distortion due to overloading is 1 volt p-p.

17. The maximum undistorted output voltage of the vertical amplifier generally does not produce vertical deflection in excess of 5". Maximum deflection of 4" will provide adequate utilization of the screen area.

18. A slight overshoot or ringing may be evident with high-frequency square-wave inputs. This effect should not exceed 8%. Keep in mind, however, that sometimes the square-wave generator may be at fault and this should be checked before attributing the effect to the scope.

19. At maximum gain settings, the sensitivity of the amplifiers is very high. Under these conditions stray pickup may produce patterns on the screen when no signal source is connected to the vertical input terminals. This is normal and does not interfere with the scope operation.

OPERATION

NOTE: To obtain proper results with your "scope", it is advisable to become acquainted with the functions and correct use of the panel controls and terminals by making some simple tests. These tests will also serve to assure you that the instrument is in proper working condition. Do not attempt this procedure with kits before all final checks have been completed and all initial adjustments have been made as described in the MAINTENANCE section.

1. Set the INTENSITY, VERT. GAIN, and HOR. GAIN controls at their furthest counterclockwise positions.

2. Set the FOCUS, V-POS, and H-POS, controls at the center of their ranges. All other controls may be set at any position.

3. Insert the power cord into a 105-125 volt, 50-60 cycle ac outlet.

WARNING: This instrument will not operate, or will operate improperly and even be seriously damaged if connected to any other type of power line (such as dc, 25-cycle ac, or an ac line above 125 volts).

4. Turn the POWER control clockwise (on). The pilot lamp should light. (Note scale-illumination control by potentiometer attached to POWER switch.) Allow the unit to warm up for about one minute. Then gradually turn the INTENSITY control clockwise until a spot appears somewhere on the screen of the cathode ray tube (CRT). If the spot does not appear, adjust the V-POS and H-POS controls slightly, as it may be off screen.

NOTE 2: At low sweep frequencies, flickering of the pattern is normal due to the slow writing speed at the spot and the persistance of the screen, which together are insufficient to cause the motion to blend into a fixed image.

10. With the single sine wave pattern locked in, switch the HOR. selector from +(INT.) to -(INT.). The same wave-form should appear, but displaced by 180°.

11. With the single sine wave pattern locked in, switch the HOR. SELECTOR to the 60 CPS SYNC position. Turn the PHASING control and note the shift in starting point of the displayed waveform.

12. Set up the "scope" controls as in paragraph 8, adjusting the PHASING control for a broad ellipse. Then set the INTENSITY control at minimum. From an audio oscillator, apply about 3 volts at 300 cps between the INT. MOD. binding post and ground, and then gradually advance the INTENSITY control until a broken-line ellipse is seen on the screen. Carefully adjust the frequency until the broken lines stand still. Note that there are 5 such lines. This indicates that the ratio between the frequency applied to the INT. MOD. binding post and the frequency applied to the V. INPUT binding post (60 cps) is 5. The INT. MOD. binding post may be used for inserting timing markers on a trace or determining the frequency of an unknown signal.

CAUTION: In any application where a signal is applied to the INT. MOD binding post, the INTENSITY control should first be set at minimum and then advanced until the desired intensity is obtained.

13. TO OPERATE the internal calibrator for measuring peak-to-peak voltage, use the following procedure: (p-p is an abbreviation for peak-to-peak.)

MEASUREMENT OF P-P VOLTAGES: (a) Set the VERT. ATTEN. at CAL. This operation injects a 0.4 volt p-p sine wave of power-line frequency into the vertical input circuit at a point following the vertical step attenuator but preceding the vertical gain control. (b) Set the HOR. SELECTOR at "+" and the HOR. GAIN control at zero (so that the pattern on the screen is simply a vertical line). (c) Adjust the VERT. GAIN and VERT. POS. controls until the vertical line extends exactly 4 major divisions (a division is 1 inch) on the calibrated screen.

You have now standardized the sensitivity of the vertical amplifier to permit direct p-p voltage measurements. Do not touch the VERT. GAIN controls while voltage measurements are being made, as any disturbance of the setting makes it necessary to recalibrate the vertical amplifier.

The p-p amplitude of a signal voltage applied to the V. INPUT terminals may be read as follows. Set the VERT. ATTEN. selector at a position that gives a pattern under 4 inches in height, without touching

14836

the VERT. GAIN control. Use the VERT. POS. control to place the bottom of the pattern on the lowest graduation of the calibrated scale. If the VERT. ATTEN. selector is at the 1 position, full scale is 0.4 volts p-p (4 inches). At the 100 position, full scale is 400 volts p-p.

MEASUREMENT OF P-P VOLTAGES ABOVE 400 VOLTS : Steps a and b are the same as when measuring voltages under 400 volts p-p. In step c, however, the VERT. GAIN control is adjusted for a deflection that is a convenient fraction of full scale. At most, this deflection should be as many times smaller than full scale as the expected value of the unknown voltage is larger than 400 volts p-p. The VERT. ATTEN. is then set at 1000 and the p-p deflection of the unknown signal is read off the calibrated screen.

The ratio of this deflection to the deflection set at calibration is then multiplied by 400 to obtain the amplitude of the unknown signal in volts p-p. EXAMPLE: The deflection set at calibration is 10 divisions or 2 inches. With the VERT. ATTEN. set at 1000, the p-p deflection of the unknown signal is 20 divisions or 4 inches. The amplitude of the signal is equal to (20/10) X 400 = 800 volts p-p.

NOTE: If the signal under observation is a sine wave (only), the rms value of the amplitude may be obtained by dividing the p-p value by 2.8.

APPLICATIONS

General: The oscilloscope is an instrument designed for viewing electrical oscillations and transients. Phenomena having a repetition rate from a few cycles per second to several megacycles per second may be displayed on a scope.

Waveform Investigation: When the output of the internal sweep generator is fed to the horizontal channel, the pattern on the screen is actually a graph showing the variation with time of the instantaneous amplitude of the signal applied to the vertical channel. The sweep frequency is usually a sub-harmonic of the signal frequency, so that several complete cycles of the signal are displayed on the screen.

Display of Waveforms: Displaying a waveform means obtaining a picture that shows how the amplitude of the signal under observation varies with time. It is generally most convenient to use a time-base signal that varies linearly with time, so that equal intervals of time are represented on the screen by equal intervals of distance along the same axis. The sawtooth output of the sweep generator gives such a time-base on the horizontal axis, the time (in seconds) represented by the overall horizontal deflection being equal to the reciprocal of the sweep frequency (in cycles per second).

Figure A

Figure B

If the frequency of the observed signal is equal to the sweep frequency, one complete cycle will be observed on the screen. If the frequency of the applied signal is twice the sweep frequency, two complete cycles will be obtained on the screen, and so on. Figure A is a drawing of a sine wave applied to the vertical plates and a sawtooth wave of the same frequency applied to the horizontal plates. Figure B is a drawing showing the resultant pattern when the frequency of the sawtooth is one-half that employed in Figure A. Changing the frequency of the sawtooth causes the display of two waveforms.

In these figures, points that occur simultaneously are numbered the same. The circle represents the tube screen. If simultaneous projections were drawn from every point on each wave, the intersections would trace out the sine waves shown in the circles. The sections of the sawtooth between 1 and 4 in Figure A and between 1 and 9 in Figure B are the sweep sections during which the displays are produced. The sections of the sawtooth between 5 and 1 in Figure A and between 9 and 1 in Figure B are the sections during which the beam is returned very rapidly to the starting point at the left-hand side of the screen. The return trace appears on the screen as a fine horizontal line.

CONCLUSIONS

For all phases of electronics it is absolutely necessary that the operator be thoroughly familiar with the operation of the oscilloscope and be skillful in using it. Review this experiment several times until you have become accustomed to using and adjusting the "scope."

QUIZ

1. Make a list containing all the controls associated with the 430. State the specific function of each.
2. What is a Lissajous pattern and where is it used?
3. Explain several practical applications of an oscilloscope.

14838

EXPERIMENT #2 FREQUENCY AND PHASE DETERMINATION

OBJECTIVE

To learn how to use the oscilloscope to find unknown frequencies and to determine phase differences.

INTRODUCTION

It must be remembered that ac has basically three characteristics. These are:

a. Amplitude or magnitude
b. Frequency (repetition with time)
c. Phase relationship

Conventionally the term ac is applied to both current and voltage. A typical sinusoidal alternating waveform is shown below:

FIG. 1

Beginning at point 1, the amplitude rises at a sine-wave rate (sinusoidal) where it reaches its positive peak ($C + E_{max}$); from this point it then decreases to its NO power point (3) and then proceeds to its second maximum power point ($-E_{max}$), returning to zero at (5); this then repeats. T is 360° rotation, a full cycle consisting of two alternations, points 1 to 3 and 3 to 5. The time required to complete one cycle is equal to T.

$$T = \frac{1}{f}$$

where T = time in seconds
f = frequency in cycles/second

EXAMPLE:

60 cycles per second power line in every household:

$$T = \frac{1}{f}$$

$$T = \frac{1}{60}$$

$$T = .0167 \text{ second or } 16.7\ \mu\text{sec}$$

One alternation would be .5T, or 8.35 μsec

Lissajous Patterns: Another type of fundamental pattern is obtained when both the vertical and horizontal deflection voltages are sine waves that are related in frequency as follows: one frequency is a whole-number multiple of the other; one frequency is a simple fraction of the other. When one or the other of these conditions is fulfilled, stationary closed-loop patterns are obtained. These patterns are called Lissajous figures after the 19th century French scientist. They are particularly useful in determining the frequency ratio between two sine-wave signals. If the frequency of one signal is known, the frequency of the other signal can easily be determined from the frequency ratio. Usually the known signal is applied to the horizontal channel and the unknown signal to the vertical channel. The shape of the pattern changes with the phase relationship between the known and unknown signals. For example, all the patterns shown in Figure 2 (and those intermediate) are possible with a frequency ratio of 1:1 if the phase differences indicated exist.

Fig. 2

In general to determine the frequency ratio from the Lissajous figure, count the number of points of tangency to horizontal and vertical lines, drawn or imagined (See Figure 3). Points of tangency at the top of the figures result from the unknown frequency applied to the vertical channel. Those at the side of the figure result from the known frequency applied to the horizontal axis. The following relationship holds true in all cases:

$$\frac{\text{V axis freq.}}{\text{H axis freq.}} = \frac{\text{V pts. of tangency}}{\text{H pts. of tangency}}$$

14840

As an example, take Figure 3 C, which shows four points of tangency at the top and one point at the side. This indicates that the unknown frequency applied to the vertical axis is four times the known frequency. In Figure 3 F, one point of tangency at the top and four at the side indicate that the unknown frequency is one-fourth the known frequency.

Fig. 3

MATERIAL REQUIRED

Oscilloscope
Audio Signal Generators (2)
Accessory Kit

PROCEDURE

1. Place the vertical input selector on internal calibrate and obtain a 2-inch sine-wave pattern.
2. Through the use of the frequency selector control, stabilize the trace until one wave is present. (This is always the ac line frequency 60 hz)
3. Without touching the frequency range or fine frequency control, place the vertical control off calibration or line to vertical input. Connect the audio signal generator (A.S.G.) into the vertical input jack.
4. Tune the A.S.G. until one wave is observed on the oscilloscope's face. Read the calibrated A.S.G. frequency. It should be at 60 hz.
5. Tune the A.S.G. to 120 hz and note the number of waves that appear on the face during the same time as the 60 hz appeared. This shows that, if a period of time is calibrated on the oscilloscope, other "unknown" frequencies can be read from the face of the oscilloscope.
6. Repeat step #5 for 180, 240, 300 and 360 hz.
7. Set up the following pictorial.

CUSTOMER FINANCIAL RECORD

One method of keeping efficient financial data is a customer file. All available information should be recorded so that there is an accurate record on which to base charges.

Customer's Name _____ Phone _____

Address _____

Job received _____ _____
(Description) (Date)

Hours worked _____

Materials supplied _____ Cost $ _____

_____ $ _____

_____ $ _____

Total $ _____

Bill rendered _____ Paid _____ $ _____
(Date) (Date) (Amount)

0841 1481

FIG. 4

8. Lissajous patterns are used in checking phase or frequency differences between known and unknown frequencies. Set the A.S.G. to a frequency of 100 hz sine-wave output.
9. Adjust the vertical gain to obtain a 1½ inch deflection.
10. Adjust the second A.S.G. to a frequency of 200 hz by means of the pattern. Refer to Figure 3.
11. Set up the following Lissajous ratios and draw the resultant oscilloscope traces.

V:H::1:2 =

(100 : 200)

1:3 =

_____ : _____

1:4 =

_____ : _____

2:1 =

_____ : _____

3:1 =

_____ : _____

4:1 =

_____ : _____

2:3 =

_____ : _____

3:2 =

____ : ____

4:5 =

____ : ____

5:4 =

____ : ____

12. Have your instructor turn A.S.G. to some unknown frequency. Find, using the Lissajous pattern, the unknown frequency. Instructor will initial.
13. Construct the following circuit, used for phase shifting.

FIG. 5

FIG. 6

14. Refer to Figure 2's traces, then slowly adjust R_1 on Figure 5 from minimum to maximum. Observe the trace, starting the phase-shift approximately at maximum and 50% resistance.
15. Change the input frequency to 500, 1000, 5000, and 10K repeating step #14 for each of the frequencies.

CONCLUSIONS

Frequency determination is widely used in industry when adjusting trap and filter circuits.

It is often necessary to inspect the phase of the voltage in respect to the current in an inductive or capacitive circuit, to view the degree of lead or lag.

14843

EXAMPLES:

FIG 7

14844

QUIZ

1. Can Lissajous figures be used to determine the frequency of a 1KHZ signal if the known frequency is 3KHZ? If so, how?
2. Explain why a diagonal line is formed on the oscilloscope face when testing two frequencies 180° out of reference phase.

16845

EXPERIMENT #3 AC VOLTAGE (RMS, PEAK, AND PTP)

OBJECTIVES

To understand the relationship between the effective value (RMS) and the peak-to-peak value of voltage and current in an ac circuit.

To develop a working knowledge of alternating and direct current.

INTRODUCTION

Root mean square (RMS), or effective value, is the most common method used to measure ac sources. The 115-volt ac house outlet power is a common RMS value. When an electric heater consumes 2000 watts at 20 amps., the 20 amps is an RMS value. Normally any 110-volt ac voltage or current that has no designation is assumed to mean an RMS value.

By the use of higher order mathematics, it is found that the RMS value is .707 of maximum. Conversely, RMS times 1.414 equals maximum. When using an oscilloscope presentation, it will be especially useful to be able to convert to RMS value.

EXAMPLE: (two methods)

PTP = 20v (maximum to maximum) as measured on an oscilloscope.

A. 20 X .5 X .707 = 7.07 volts RMS

B. 20 X .3535 = 7.07 volts RMS

MATERIALS REQUIRED

Audio frequency signal generator
Power supply
Breadboard
Accessory kit
VTVM

PROCEDURE

1. Set up the equipment as shown in Figure 8.

2. Adjust the A.S.G. to 3.5 volts RMS, or approximately 10v peak-to-peak at 1000 hz.
3. Adjust the oscilloscope for two complete cycles, 2 divisions high (2 inches). Do not move the vertical gain control again, as the scope is now calibrated; 1 inch = 5 volts P.T.P. or 1.75 volts RMS.
4. With the oscilloscope measure both the RMS and P.T.P. value across each resistor on the breadboard.
5. Recalibrate the oscilloscope by inserting 6.3 volts ac RMS into the oscilloscope from the power supply (Fil.).
6. Place the 6.3 volts across R_1 through R_3.
7. Repeat step #4.
8. Add all resistor P.T.P. readings and all RMS values. Do they keep the same relationship of .707 $volts_{peak}$ = RMS?

Fig. 8

CONCLUSION

Although an oscilloscope displays all voltages or currents maximum to maximum, it can be calibrated to measure peak or RMS values with ease.

QUIZ

1. An oscilloscope is accurate within 5% when reading voltages and currents. If the oscilloscope measured 25 volts P.T.P., which was then converted to RMS, on paper, what would a no-tolerance, ac RMS meter read, minimum and maximum, and still be correct?
2. Point out any differences detected during calculation and observation when running this experiment.

EXPERIMENT #4

INDUCTANCE, INDUCTIVE REACTANCE, AND IMPEDANCE

OBJECTIVE

To observe the effect of inductance in an alternating current circuit.

INTRODUCTION

A coil of wire possesses inductance (L) and inductive reactance (X_L). Inductive reactance is measured in ohms and is dependent on the applied frequency and the inductance.

$$X_L = 2\pi fL$$

The amount of X_L (ac opposition to a changing current) has a great influence on circuit current and tends to filter or smooth it.

Inductive reactance never appears alone in a circuit. Any coil that has inductance must also contain wire resistance. The combined opposition, X_L and R, is known as impedance (Z) and is found generally by:

$$Z = \sqrt{R^2 + X_L^2}$$

or

$$Z = \frac{E}{I}$$

Inductive reactance is directly proprotional to frequency. That is, inductive reactance (X_L) increases with frequency, as is illustrated in Figure 9.

FIG. 9

14848

MATERIAL REQUIRED

Breadboard
Accessory kit
A.S.G.
Oscilloscope
VTVM and VOM

PROCEDURE

1. Set up the equipment for observing voltage, current, and impedance relationships in a series L-R circuit.

Fig. 10

2. Adjust the A.S.G. for 1200 hz and 3.5 volts RMS (10v P.T.P.).
3. Calibrate the scope for .5 volts P.T.P. = 1 small scale division. This is done by adjusting the vertical gain for 20 small scale divisions whereby:

20 = 10	volts P.T.P. or	3.5	volts RMS
10 = 5	volts P.T.P. or	1.75	volts RMS
5 = 2.5	volts P.T.P. or	.875	volts RMS

4. Measure the total and individual dc resistances present in the circuit (L and R).
5. Calculate the circuit current, I_L, I_R, E_L, and E_R.
6. Apply power; then measure E_L and E_R.
7. Record and explain any difference between the calculated and measured values.

8. Calculate X_L, then plug it into the formula for total opposition, Z.
9. Transpose the formula for impedance, $Z = \frac{E}{I}$; calculate the circuit current I.
10. Knowing total I series, calculate E_R and E_L.
11. Connect the oscilloscope across each component and measure each P.T.P. (Note the phase-shift between the components).
12. Draw a vector diagram of the voltage phase relationship of the circuit, using the circuit current as a horizontal zero time reference.
13. Replace the 15K resistor with a 47K resistor and repeat steps #2 through #12.

CONCLUSIONS

The effect of ac introduced into a circuit, differs significantly from the effect of dc. The inductive reactance of the circuit limits the change of the current in the circuit and it cannot follow the ac voltage source. The current actually lags the circuit voltage by up to 90°, dependent on the relationship between L and R. It may be said— the voltage in an inductive circuit <u>leads</u> the current (E.L.I.).

QUIZ

1. Would you expect the inductance to rise or fall if the frequency to the circuit were increased?
2. If the frequency were increased, what would happen to X_L? Z?
3. A coil has 10 ohms resistance and a reactance of 13 ohms at 60 hz. What is the circuit current with 30 volts dc applied?
4. In a circuit having 100 ohms X_L and 100 ohms R, what will be the phase angle of the current with reference to the voltage?
5. What is the Z of a series circuit containing X_L = 10 henry, R_1 = 10 ohms and R_2 = 100 ohms?

414850

EXPERIMENT #5 PARALLEL L-R CIRCUIT ANALYSIS

OBJECTIVE

To observe parallel L-R circuits in a practical environment.

INTRODUCTION

A parallel L-R circuit is similar to parallel-connected resistors in dc circuits. In resistor circuits the voltages present across each branch are equal and in phase with each other. However, in an ac circuit which has an inductor in parallel with R, the current in the "L" branch lags the branch voltage as well as all other resistive branch voltages. This results in the inductor-branch current lagging the voltage in the inductive branch, the current in the resistive branch, and the source voltage by up to 90° (theoretical).

MATERIAL REQUIRED

Audio frequency generator
Oscilloscope
Breadboard
Accessory kit
VTVM and VOM
Table of Trignometric Functions

PROCEDURE

1. Set up the equipment for analysis of parallel L-R circuits.

Fig. 11

R_1 = 5.1K
R_2, R_3 = 1K
R_4 = 560
L_1 = 4H

2. Adjust the signal generator to 400 hz and maximum output voltage.
3. Adjust the oscilloscope for 2 cycles of presentation.
4. Calculate X_L and R in series to find Z. (Branch 2)
5. Calculate R—branch #1.
6. Calculate I—branch 2 and I—branch #1.
7. Draw a vector diagram consisting of I-Branch #1 versus I-Branch #2. Work out the line current.
8. Illustrate, on the vector diagram, the relationship of I-line to I-Branch #1 and I-Branch #2.
   EX: I_{Line} leads $I_{Branch\ 1}$ by 30° and lags $I_{Branch\ 2}$ by 60°.
9. Calculate the total Z by the use of Ohm's Law and the impedance formula. This should be less than either branch. Record.
10. Set up the equipment shown below.

Fig. 12

R_1 = 5.1K
R_2, R_3 = 1K
R_4 = 560
L_1 = 4H

11. Adjust the oscilloscope controls for an in-phase Lissajous pattern.
    Note for part A of Figure 13:
    The line (Lissajous Pattern) is 45° when both horizontal and vertical deflections are equal.

14852

Fig. 13

NOTE: THIS PATTERN IS SHIFTED 180°

Fig. 14

12. Move the horizontal input lead to the top of R_3 and adjust the oscilloscope gain controls for a 90° phase-difference Lissajous Pattern (part C). Recall that the phase of the resistive branch is the same as the applied voltage; therefore the vertical input is a sample of the voltage applied to the circuit.
13. Move the horizontal input lead to the left terminal of R_4. This samples the phase of the line-current in respect to the applied voltage. Note: Because of the placement of the oscilloscope ground reference lead, the horizontal-input wave-form is 180° out of phase from the vertical-input wave-form.
14. Draw the oscilloscope pattern accurately and find the phase angle by using the Y-intercept over Y-amplitude method to determine the sine trignometric function.
15. Compare this to your calculated value.

CONCLUSIONS

In a parallel circuit the voltage is the same across each branch and is used as the reference when analyzing such circuits. The current through the resistive branch is in phase with the reference voltage, and the current through the inductive branch lags the reference voltage. The line current, which is the vector sum of the branch currents, is greater than either branch current and lags the applied voltage. The total impedance is less than the opposition of either branch.

14853

QUIZ

1. An R.F. choke coil has a dc resistance of 1000 ohms with an inductance of 500 millihenrys. This coil is paralleled with a 2K ohm resistor. When 50-volt ac is applied at 1 megahertz, the line current is _____ amperes with a current lag of _____° behind E_{line}.
2. Why is the phase of a parallel or series L-R circuit important?
3. A coil with a reactance value of 50 ohms is connected across a 100-volt source. A dc resistor of 10 Ω is in series with the coil. A 20-ohm resistor is in parallel with this combination. What is circuit Z, I_T, and E_R for the 10-ohm resistor?

EXPERIMENT #6 COMPLEX L-R CIRCUITS

OBJECTIVE

To reinforce the knowledge gained in Experiment #5, using Inductance in alternating-current circuits.

INTRODUCTION

Although an inductor has the same properties when placed into a series or parallel ac circuit, the circuit effect differs in both cases. In analysis they must be treated electrically as individual circuits. Combining the two into one complex circuit will further alter the concept.

MATERIAL REQUIRED

Audio frequency signal generator
Vacuum-tube voltmeter (VTVM)
Breadboard
Accessory kit
VOM

PROCEDURE

1. Construct the following circuit.

$R_1 = 15K$ $L_1 = 4H$
$R_2 = 5.1K$ $L_2 = 7H$

FIG. 15

14855

2. Calculate Z_T, I_T, E_{R1}, E_{R2}, I_{L2}.
3. Apply 1 Khz at maximum output power to this combination circuit.
4. Measure all measurable values and compare them with the calculated values.
5. Draw a vector diagram using the line voltage as the reference.
6. Change the line frequency to 10 Khz.
7. Repeat steps #2 to #6.
8. Analyze the effect of varying the frequency on this circuit, by raising and lowering the input frequency 500 hz.

CONCLUSION

In the series portion of the circuit, X_L varies linearly with frequency, consequently line current varies inversely with frequency. The parallel portion is characterized by the opposite of the series L-R circuit characteristics.

QUIZ

Review the circuit under question, in its entirety. Design your own circuit if necessary to complete your synopsis.

14856

EXPERIMENT #7 R-C SERIES CIRCUITRY

OBJECTIVE

To observe the effects of capacitance in a series R-C circuit.

INTRODUCTION

The property of a capacitor is to try or tend to keep the voltage (either ac or pulsating dc) at a constant value. The nature of capacitance, however, causes the voltage present in this circuit to do the opposite of inductance, or to lag the current. It might be well to remember this little memory-aid:

ELI - ICE - MAN

This refers to the current/voltage relationship in an inductive and capacitive circuit. E (L) I: voltage leads current in an inductive circuit. I (C) E: current leads voltage in a capacitive circuit.

The amount of opposition a capacitor offers to alternating current is measured in ohms and symbolized as X_C. The basic formula used to find the amount of X_C is:

$$X_C = \frac{1}{2\pi fC} \quad \text{or} \quad \frac{.159}{fC}$$

In a series circuit containing both R and C, an increase in the frequency (rate of change of the input) will cause a decrease in X_C and a consequent increase in the line current.

FIG. 16

14857

An increase in capacitance will have the same effect on the circuit current. It will also decrease the phase-lag between E and I. Z is found by:

$$Z = \sqrt{R^2 + X_C^2}$$

MATERIAL REQUIRED

A.S.G.
Breadboard
Oscilloscope
Accessory kit
VTVM
VOM

PROCEDURE

1. Construct the following circuit:

FIG. 17

2. Set the A.S.G. to 480 hz and maximum output.
3. Set the oscilloscope trace for several cycles of ac and a height, when placed across the A.S.G., of 4 inches. Record the P.T.P. ACROSS EACH COMPONENT.
4. Calculate X_C, Z , I , E_{R1} and E_{C1}.

14858

5. Measure all measurable values.
6. Calculate the amount of voltage lag in this circuit.
7. Parallel a 1-emf capacitor across C_1.
8. Repeat steps #2 to #6.
9. Change the input frequency 10% and measure all effects observable.

CONCLUSION

In a series R-C circuit the most probable major influence is the input frequency, determining X_C and Z. It must be remembered: AT ALL TIMES E and I are in phase in a pure resistance, regardless of its circuit placement. Inductance or capacitance may cause the phase to shift.

QUIZ

1. A .001 mf capacitor is 45° out of phase with a shunt resistor, 10K. What is the input frequency?
2. In a 1 Khz circuit, a capacitor opposes the change in voltage by 750 ohms. What size is the capacitor?

EXPERIMENT #8 PARALLEL R-C CIRCUITRY

OBJECTIVE

To observe the effect of alternating voltage and current in a parallel R-C circuit.

INTRODUCTION

A resistor and a capacitor wired in parallel have the combined properties of both components. The capacitive reactance, being inversely proportional to frequency, will pass more current as the input frequency is raised. This rise is non-linear or exponential in nature. The branch voltages, as in ALL parallel circuits, are equal and in phase with each other. As with other capacitive circuits, the current in the capacitive branches leads the branch voltage by up to 90°.

MATERIAL

A.S.G.
VTVM and VOM
Breadboard
Accessory kit

PROCEDURE

1. Set up the equipment as shown below:

Fig. 18

R_1 = 3.3K
R_2, R_3 = 1K
R_4 = Jumper
C_1 = 0.1 mfd

2. Set the A.S.G. to 1Khz and maximum output.

3. Calculate X_{C1}, Z, I, E_C and E_{R3} of the capacitance branch.
4. Calculate E_{R1}, E_{R2}, I_{R1}, and R_T of the resistive branch.
5. Calculate the total L, Z, and the phase angle of the circuit.
6. Measure all measurable values calculated.
7. Compare in chart form all calculated and measured values. Explain any differences.

CONCLUSION

In a parallel R-C circuit the voltage is the reference in the circuit, due to parallel-circuit characteristics. The resistive branch current is in phase with the total voltage (combined R_1 and R_2 voltage). The total Z in the circuit will be less than either branches R or C, due to the reciprocity of the component placement arrangement.

QUIZ

1. If C_1 is doubled, what happens to Z_T? I_T?
2. If the frequency is changed 20%, the total Z will change _____ ohms. Is it a linear change?
3. What effect has a change in the resistive circuit's ohmic value on the total circuit current?
4. Where is the circuit Z greater, at the lower frequency line current or the higher?

EXPERIMENT #9 R-C COMBINATION CIRCUITRY

OBJECTIVE

To analyze a circuit containing parallel R-C components in series with each other.

INTRODUCTION

By incorporating both the series and parallel R-C circuit laws independently, a complex circuit can be reduced to an understandable circuit.

MATERIAL REQUIRED

A.S.G.
Breadboard
Accessory kit
VOM and VTVM
Oscilloscope

PROCEDURE

1. Construct the following circuit:

R_1 = 1K C_1 = .1 MFD
R_2 = 1K C_2 = .01 MFD

FIG 19

14862

14863

2. Set the A.S.G. to 150 hz and maximum output. NOTE: Monitor the output power from the A.S.G. as it may change due to the shorting effect of capacitance at the higher frequencies.
3. Calculate all possible values, including the voltage-divider action of R_1 - C_1 and R_2 - C_2 combinations. (RMS value)
4. Measure all measurable values, including the RMS from B to C.
5. Open the circuit at point B and measure the current at this point. Calculate .707 of this value.
6. Vary the A.S.G. above and below 150 hz until the above calculated values are reached. Record.

CONCLUSION

In R-C circuits, as the frequency increases, the phase angle (which in reality is a comparison between the ac and dc circuit resistance) will decrease. This is due to the shunting effect of capacitance as the frequency changes. There are many advantages to be gained from either series or parallel circuits using capacitance. They are used commonly as filters and ac voltage-divider circuits.

QUIZ

1. Design a voltage-divider circuit using two capacitors in series across the 110-volt ac line, so the voltage across one of the capacitors is 11 volts ac.
2. Repeat #1 but have one of the capacitors 8 mf.

NATIONAL BUREAU OF STANDARDS-1963-A

EXPERIMENT #10 SERIES R-L-C CIRCUITRY

OBJECTIVE

To observe the effects of resistance, inductance, and capacitance in a series circuit.

INTRODUCTION

Series R-L-C circuits find their greatest application as resonant circuits and phase-shifting circuits. In all circuits of this type, the reference phase will be "I" line.

MATERIAL REQUIRED

A.S.G.
Breadboard
VTVM and VOM
Oscilloscope
Accessory kit

PROCEDURE

1. Construct the following circuit:

Fig. 20

2. Set the signal generator to 500 hz at 3.5 volts RMS. Monitor this voltage throughout the experiment to assure constant output voltage.
3. Calculate X_L, X_C, R, Z, and I_T.

214

4. Measure all measurable values at the 500 hz input frequency.
5. Calculate E_{R1}, E_{L1}, and E_{C1}.
6. Measure with the oscilloscope all calculated values from step #5.
7. Compare all measured and calculated values.
8. Change the input frequency to 1400 hz.
9. Repeat steps 3 to 7.

CONCLUSION

Series-circuit laws still apply, but the reactances must be dealt with in a different manner due to ELI - ICE - MAN. If each is out of phase by up to 90° from a dc resistance, one leading and one lagging, they are in direct opposition to each other. If the oppositions are equal they may neutralize each other.

QUIZ

1. Draw a vector diagram containing R, X_C, X_L at both 500 and 1400 hz.
2. What is the phase relationship between circuit current and source voltage?
3. Between circuit current and E_C?
4. What would be the effect on the circuit current, source voltage, and I_c if R_1 were removed?

14865

EXPERIMENT #11 PARALLEL R-C-L CIRCUITRY

OBJECTIVE

To acquaint the student with the usefulness of R-C-L parallel circuits as filter networks.

INTRODUCTION

In a circuit of this type the impedance changes line and branch currents considerably as the line frequency changes. Depending upon the direction of the line frequency change, the circuit may look either capacitive, inductive, or resistive in nature. The net reactance is the difference between the reactive components.

MATERIAL REQUIRED

A.S.G.
Breadboard
VTVM and VOM
Oscilloscope
Accessory kit

PROCEDURE

1. Construct the following circuit.

Fig. 21

R_1 = 22K
R_2, R_3, R_4 = 1K
R_5 = 25 Ω

L_1 = 4H
C_1 = .01 mfd

14866

2. Adjust the signal generator output for 1 Khz at 10 volts P.T.P. output.
3. Calculate all values, including lead or lag of the E source - I source relationship.
4. Measure all measurable values.
5. Compare (in chart form) the results obtained in steps 3 and 4.
6. Change the input frequency to 500 hz and 1500 hz (output 10 volts P.T.P.)
7. Repeat steps #3 to #5 for each of the new frequencies.

CONCLUSIONS

In a parallel reactive circuit, current is controlled by the component having the least reactance.

QUIZ

1. The controlling component in the experimental circuit at low frequencies is the _____.
2. If the input frequency were raised to 5 Khz, would the circuit look capacitive or inductive? Why?
3. The generator output drops to 5 volts P.T.P. but the frequency stays the same. State the circuit and component effects that would take place.

14867

EXPERIMENT #12 SERIES RESONANCE

OBJECTIVE

To determine the operating characteristics of a series-resonant circuit at and off resonance.

INTRODUCTION

Resonant circuits are used extensively in electronics as frequency-discrimination circuits. By selecting one frequency or a narrow band of frequencies from the total spectrum, we can tune a radio or TV station. Resonant circuits are generally used at RF (radio-frequency) rather than AF, but will be used in this experiment at the lower frequencies.

MATERIAL REQUIRED

A.S.G.
VTVM and two VOM's
Oscilloscope
Breadboard
Accessory kit
Graph paper
Multimeter panel

PROCEDURE

1. Construct the following circuit.

Fig. 22

14863

2. Connect a VOM across both L_1 and C_1 (ac volts).
3. Set the signal generator to 10 volts P.T.P. and adjust the frequency until E_{L1} and E_{C1} read the same. (May be at or near zero)

   NOTE: The VTVM must monitor the 10-volt P.T.P. throughout this experiment.

4. Calculate X_L, X_C, Z, I_T, E_R, E_{C1}, and E_{L1} at this frequency.
5. Measure all calculated values.
6. Compare steps #4 and #5.
7. Adjust the signal generator to both a higher and lower frequency until the upper and lower half-power points are reached. (70.7%I_T) Record the generator frequency at each of these points.
8. Determine the bandwidth and bandpass of this circuit.
9. Calculate the circuit Z.
10. Change R_1 to 10 ohms. Repeat steps #7 through #9.
11. Change R_1 to 10 K.
12. Repeat steps #7 through #9.
13. Make a graph for each of the three trials (10Ω, 1K, and 10K) of impedance versus frequency.

CONCLUSION

Characteristics of all series circuits at resonance:

A. $X_L = X_C$

1. $X_L = 2\pi FL$
2. $X_C = \frac{1}{2\pi FC}$
3. $2\pi FL = \frac{1}{2\pi FC}$
4. $FR = \frac{1}{2\pi\sqrt{LC}}$

   Where FR = resonance frequency

B. The Z across the circuit is low or zero (equals the resistance).
C. The voltage drop across the circuit is low or zero.
D. The current flow from the source is high or theoretically infinite. (R = 0)
E. The circuit acts as a purely resistive (no reactance) load to the source and has a power factor = 1.

14869

F. The voltage drop across either reactance is equal to E = IZ and may be greater than the source voltage.

G. The phase angle of the current and voltage as seen by the source is 0°, or in phase.

The bandwidth is the frequency range that the current is passing above the half-power points.

EX: FR = 1000 hz, L.S.B. = 800 hz,
U.S.B. = 1200 hz, B.W. = 400 hz

Circuit bandpass is the actual frequencies that the circuit is working, or capable of working, at the values given.

EX: FR = 1000 hz, L.S.B. = 800 hz,
U.S.B. = 1200, B.P. = 800 to 1200 hz

QUIZ

1. A 7.5-ohm resistor is connected in series with a 150-microhenry coil and a 169 mmf capacitor to a 1-volt variable-frequency source. Determine F, I_T, X_L, X_C, Q, E_R, and E_C at the resonant frequency.
2. The voltage drop across the coil or capacitor is _____ times greater than the applied voltage in question #1.
3. Why does the impedance increase on both sides of resonance?
4. In a series R-L-C resonant circuit operating above resonance (FR), the voltage developed across C drops. Why is this?
5. The resistance in a series resonant circuit cannot be changed. However, it is possible to raise the Q, narrow the B.W., and keep the same resonant frequency (FR) by increasing the L-to-C ratio. Explain.

EXPERIMENT #13 PARALLEL RESONANCE

OBJECTIVE

To analyze a practical parallel resonant circuit and observe its resonant characteristics.

INTRODUCTION

Parallel resonant circuits are used for the same purpose as series resonant circuits, frequency discrimination. However, the circuit characteristics differ quite distinctly from the series resonant circuit.

Example of Z and I:

Theoretical

FIG 23

FIG. 24

Practical

FIG. 25

FIG. 26

0r841 14871

MATERIAL REQUIRED

A.S.G.
VTVM and two VOM's
Oscilloscope
Breadboard
Accessory kit
Graph paper

PROCEDURE

1. Construct the following circuit.

Fig. 27

NOTE: VTVM-2 and -3 may be VOM's (20K ohms/volt)

2. Adjust the signal generator to a frequency where meter 3 reads minimum. At this frequency set the generator amplitude at 10 volts P.T.P. or at maximum if 10 volts P.T.P. cannot be achieved. (Keep this constant throughout the experiment.)
3. Calculate X_L, X_C, Z_1, and I_T at this frequency. Include R_1 and R_L in your calculations for Z_1 and I_T.
4. Calculate .707 of Z_T for the USB and LSB cut-off points.
5. Calculate I_T at the cut-off points.
6. Adjust the generator to each of these points, by monitoring the line current. Record FUSB and FLSB.
7. Calculate B.W., B.P., and circuit Q.
8. Change C_1 to a 0.1 mf capacitor.
9. Repeat steps #2 to #7. Compare the new results.

14872

10. Add R_2 and repeat steps #2 to #7. Compare the effect on the circuit with the addition of R_2.
11. Use the oscilloscope in all applications where voltage readings are required.

CONCLUSIONS

The characteristics of a theoretically "pure" parallel resonant circuit are:

A. $X_L = X_C$
B. The Z across the circuit is maximum.
C. The voltage drop across the circuit is equal to or less than the source voltage.
D. Source current is Low or Zero.
E. The current through each reactance is equal to I = E/X and will be greater than the source current.
F. The circuit acts as a pure resistive $X_C = X_L$ (zero reactance) load to the source and therefore has a power factor (P.F.)= 1.
G. The phase of source voltage and current is 0° or in phase.
H. The phase of the current and voltage of each reactance is 90°.
I. Adding "R" to either branch, lowers the Z of the whole circuit.

The transition of Z and phase characteristics near resonance (above the half-power points) is gradual for Low-Q circuits but more rapid for high-Q circuits. The circuit Q is determined by "R" in the circuit: the higher the series line (or generator) resistance, or the parallel (load) resistance, the lower the Q. However, resistance does affect circuit Q and hence the impedance. It is precisely because of the opposite effect of frequency change upon the reactances that the characteristic variations of impedance (and phase angle) occur.

QUIZ

1. A 160-microhenry coil in series with a 20-ohm resistor is connected in parallel with a 250 mm capacitor and placed across a 20v, variable frequency source. Find FR, Q, Z_T, I_T, and the branch currents at resonance.
2. Which of the following are true about a parallel R-L-C circuit operating at resonance? (theoretically)

   A. I_C cancels out I_L.
   B. The current in the inductor is 180° out of phase with the line current.
   C. The power dissipated in R_L (series with L) is greater (E source constant) than at any other frequency.

14873

D. The circuit acts purely resistive.
E. The current in L and C are greater than at any other frequency.
F. The phase angle of the applied voltage and current is zero degrees.
G. The capacitive and inductive voltages are in phase.
H. The capacitive voltage completely cancels the inductive voltage.

3. A variable capacitor has a minimum capacitance of 20 mmf and a maximum capacitance of 300 mmf. If connected across a 100 μh coil, what is the (a) highest frequency (b) lowest frequency, to which it can be made resonant?

EXPERIMENT #14 TRANSFORMER THEORY

OBJECTIVE

To analyze the principle of transformer action.

INTRODUCTION

A transformer consists of two or more inductances in proximity to each other. Current flowing in one inductor induces a voltage into another. Normally, the coil that is receiving the source power is called the primary (E_P) and the coil receiving this energy is called a secondary coil (E_S). Examples of schematic layout of a power transformer and its common wire color code are shown in Figures 28 and 29.

Fig. 28

874875

As shown, a single primary winding can supply several secondary windings, but it must be remembered that at best the total secondary power can never exceed the primary power.

COLOR	WINDING
BLACK	PRIMARY
RED	HIGH VOLTAGE
RED AND BLACK	HIGH VOLTAGE CENTER TAP
YELLOW	5 VOLT FILAMENT
GREEN	6 VOLT FILAMENT
GREEN AND YELLOW	6 VOLT CENTER TAP

Fig. 29

The primary and secondary windings may be wound on different types of cores to increase magnetic coupling and efficiency. The most commonly used core is laminated iron. This is used at low and audio frequencies, but at higher frequencies (RF) either powdered iron or no core is used.

The parallel dotted or solid lines between the primary and secondary coils indicate the presence of an iron core.

Some more commonly used formulas for calculating turns ratio, voltages, or currents are as follows:

A. $N = \frac{\text{Secondary turns}}{\text{Primary turns}}$ (Step-up)

B. $N = \frac{\text{Primary turns}}{\text{Secondary turns}}$ (Step-down)

C. $E_s = N \times E_p$ or $E_s = \frac{E_p}{N}$

D. $I_s = \frac{I_p}{N}$ or $I_s = NI_p$

E. $\frac{Z_p}{Z_s} = \frac{N_p}{N_s}^2$

14876

F. % efficiency $= \frac{P_s}{P_p} \times 100$

G. $\frac{T_p}{T_s} = \frac{E_p}{E_s}$ or $\frac{T_p}{T_s} = \frac{I_s}{I_p}$

H. Combining, $\frac{I_p}{I_s} = \frac{E_s}{E_p} = \frac{N_s}{N_p} = \sqrt{\frac{Z_s}{Z_p}}$

When a load is connected across the secondary of a transformer, many things happen:

a. The source emf produces primary current.
b. I_p produces a counter emf, E_c, in the primary.
c. I_p also produces a secondary voltage, E_s.
d. E_s produces I_s, through the load.
e. I_s produces its own magnetic field, which cuts the primary coil.
f. The expanding secondary field produces a counter emf, E_{cc}, in the primary (opposite to E_c but in phase with the primary source voltage).
g. E_{cc} partially cancels out E_c.
h. I_p tends to increase, due to the E_c decrease.

14877

MATERIAL REQUIRED

A.S.G.
VTVM
Oscilloscope
Breadboard
Accessory kit

PROCEDURE

1. Set up the equipment as shown below:

Fig. 30

2. Push the coils together (tight coupling) and adjust the audio generator for an output of 1 Khz at 10 volts P.T.P., or maximum if 10v cannot be realized. Measure E_{R1}.
3. Push the coils apart in steps of .25 inches, recording E_{R1}.
4. Set up the equipment as shown below.

Fig. 31

R_1, R_2 = 2.2K
R_3 = 1.5K

14878

CONCLUSION

There are three types of coupling in transformers: tight, optimum, and loose. This in effect governs the amount of induced power into secondary coils and is usually fixed during manufacture.

With a pure resistive load in the secondary, the E and I are in phase with each other and 180° out of phase with the primary voltage. Reversing the secondary leads causes an in-phase condition to exist.

QUIZ

1. What would be the result on the primary voltage if the secondary load were inductive? Capacitive?
2. Name two uses for a transformer with a 1:1 turns ratio.
3. What is the result of decreasing the secondary load resistance on the primary current? Why?
4. Can either winding of a two-winding transformer be used for the primary? Why?

14879

14880

EXPERIMENT #15

TRANSFORMER
E, I, AND Z TURNS RATIO

OBJECTIVE

To observe the relationship between primary and secondary E, I, and Z.

INTRODUCTION

The relationship between the number of primary turns and secondary turns is called the turns ratio of the transformer. When the turns ratio is known, along with the voltage, current, or impedance of one winding, the other coil's E, I, or Z can be found.

MATERIAL REQUIRED

Multimeter
Power supply
Breadboard
Accessory kit
Multimeter panel

PROCEDURE

1. Set up the equipment shown below.

Fig. 33

14380

This booklet is published primarily for use in the schools of New York State, and free copies are available to New York State school personnel when ordered through a school administrator from the Publications Distribution Unit, State Education Building, Albany, New York 12224.

6970/2/02511/9522

1485

2. Connect the VOM across the primary of T_1 (measured at the primary of T_3). Record this voltage.
3. Set T_1 dial at 25 and measure across the primary of T_2. (T_1's output)
4. Calculate the turns ratio of T_1 with the above information.
5. Set the powerstat to 50. Repeat Steps #3 and #4.

Fig. 34

1. Connect the VOM across R_1 (Breadboard) and record this voltage.
2. Calculate the turns ratio of T_3.
3. Remove R_3 from the variable power supply.
4. Adjust T_1 for 165 volts across the T_2 secondary.
5. Measure T_2 primary.
6. Calculate T_2's turns ratio.
7. Record the secondary current as indicated on the multimeter panel.

NOTE: The meter panel is set on the 100 volts ac scale and indicates one volt for each ma of secondary current.

8. Calculate I_p (T_2) from the turns ratio and secondary current.
9. Calculate T_1 primary current from the T_1 - T_2 turns ratio and T_2 secondary current (previously calculated).
10. Substitute a 5.1K resistor for the 1K resistor at R_1 on the breadboard.
11. Repeat Steps #4 through #9, part II.

14881

12. Leave the 5.1K resistor at R_1 on the breadboard. (Refer to note in Step #7, part II.)
13. Adjust the Rheostat (T_1) for 135v across the T_2 secondary.
14. Calculate the turns ratio of T_1 and T_2 as a combination.
15. The secondary "Z" is approximately 6.1K. Calculate Z_p of T_1, using the turns ratio from Step #15.
16. Substitute a 1K resistor for the 5.1K at R_1 on the breadboard and repeat Steps #14 through #16.
17. Replace R_3 on the power supply panel.

CONCLUSION

The knowledge of the relationship between E, I, Z, and turns is a prerequisite to the classification of technician, aide, or engineer. This is a unique relationship and is an expansion of the basic Ohm's Law.

QUIZ

1. A transformer has 120 volts ac applied to its primary. The secondary load circuit is open, yet measures 360 volts ac across the secondary. Measuring I_p shows a small amount of current flowing. Explain why.
2. What is the E_s of a transformer if the primary is 100v, T_p = 200 and T_S = 40?
3. If a power transformer has a step-up voltage ratio of 1:5, under load, what will be the approximate ratio of I_P to I_S?
4. A power transformer has E_P = 4400v and E_S = 220v. The efficiency of the transformer is 98% when delivering 23a of I_S. What is the value of I_P?
5. What would happen if a transformer designed for 400 hz were connected to a 60-hz line? 60 hz, to a 400-hz line? Elaborate.

14882

EXPERIMENT #16

TRANSFORMER
TYPES AND APPLICATIONS

OBJECTIVES

To examine basic types of transformers.

INTRODUCTION

The three main types of transformers are: power transformers, audio frequency transformers, and radio frequency transformers. Power transformers are used to step up or step down voltages, or both. Audio transformers are used at low frequencies (less than 20 Khz), mainly as impedance matching devices, which transfer maximum power to a load. RF transformers serve a similar function at the higher frequencies. (20 Khz to infinity)

Applications:

A. Power transformer

Fig. 35

14883

POWER SUPPLY

Fig. 36

14884

B. Audio Transformers

Fig. 37

Fig. 38

14885

C. RF transformer (T_1 and T_2)

14882

14886

Fig. 39

MATERIAL REQUIRED

VOM
Power supply

PROCEDURE

1. On the variable-power-supply (V.P.S.) panel, measure the line voltage (T_3 primary).
2. Adjust the powerstat (T_1) until the line voltage reads 50% of maximum.
3. Notice that the transformer is now effectively center-tapped, with equal voltages across each half.
4. The entire winding of T_1 is used as the primary of the auto-transformer, and only that portion below the adjustable arm is used as the secondary.
5. Connect the VOM across the secondary winding of the auto transformer.
6. Adjust R_1 for 70 volts ac.
7. Calculate the turns ratio, noticing the action of T_1, a step-down transformer.
8. Adjust R_1 for 100 volts ac.
9. Repeat Step #7.
10. Adjust R_1 for maximum and repeat Step #7. (Note that R_1 in step #10 is a 1:1 transformer)

CONCLUSIONS

Although many different types of transformers are used in electronic equipment, such devices have two functions: to transfer E or I, or to match impedance.

QUIZ

1. Is it possible to connect the primary and secondary of a conventional power transformer together to form an autotransformer? Illustrate if necessary to explain your answer, whether it be yes or no.
2. Draw the schematic symbol for:

   a. Power transformer--center tapped
   b. Audio output transformer--tapped primary
   c. RF transformer--tapped primary

ABSTRACT - This modular instructional guide was developed for use in the automobile mechanics vocational training program at the United States Reformatory in Petersburg, Virginia. The contents are arranged in modular order so that revisions can be made without interrupting the entire procedure and students can work at individual rates. Major units are: (1) Introduction, (2) Tools, (3) Fuel System, (4) Electrical System, (5) Engine, (6) Cooling System, (7) Brake System, (8) Power Flow, (9) Chassis, (10) Servicing, and (11) Trouble Shooting and Tuneup. Specific performance objectives, references, conditions, and behavior expectancies are presented for each unit. Students are expected to select pertinent information materials to aid them in the course. A training progress report chart is appended. (Not recommended for hard copy reproduction due to marginal legibility of original document.) (GEB)

ABSTRACT - Developed by electronics teachers in Camden County vocational and technical schools of New Jersey in cooperation with the Vocational-Technical Laboratory of Rutgers University, this is the first of two guides designed for teacher and student use in introducing the basic principles of electricity and electronics. Units, each consisting of three or more lessons, cover the following topics: (1) Safety, (2) Tools, (3) Atoms, Electrons, and Electricity, (4) Current and Conductors, (5) Voltage and Potential, (6) The Battery, (7) Resistance and Resistors, (8) The Metric System and Powers of Ten, (9) Reading Scales, (10) The Slide Rule, (11) Ohm's Law, and (12) Reading the Meters. The lessons contain explanatory information, assignments, questions, illustrations, and diagrams. Achievement tests are included. A continuation of this course is included in a related document, available as VT 012 903, also in this issue. (GEB)

WELCOME

Welcome to the study of electricity and electronics. This study - this course - will be like a new friend, and it will probably be the best friend of your life. For the next several years you will be learning of the properties of electricity, which are now considered by a large majority of the people on earth to be deep mysteries. Millions even consider them to be magic. You will have the satisfaction of knowing and understanding these secrets. You will be building circuits and commanding powerful forces of electricity to do your bidding.

These forces are either furnishing the power or are operating the controls of machines which produce the many thousands of things that we need or enjoy in our daily life. They are needed in the giant locomotives which transport people and necessities from city to city. They are needed in the ships which transport people and necessities from country to country; and they are needed in the space ships which explore the regions of outer space.

Tomorrow's electrician will work hand-in-hand with the scientists and engineers who will create new products, machines, and luxuries undreamed of today. The electronics technician will be interpreting the engineer's language to the producers and will be guiding their hands in the manufacturing of those wonders-to-come.

It is good to know, too, that the need for electricians and electronics men is becoming greater and greater. This situation means that salaries will be higher in this field of work.

The industrial electrician is becoming more and more respected as a highly skilled technician. His job is demanding higher skills. He is now finding that he must have a knowledge of electronics, since he is expected to service and repair many manufacturing controls that are of electronic design.

If you will inquire, you will probably find that electronic controls connected to the boilers in your school are responsible for maintaining constant heat in your classrooms.

The industrial electrician, then, is a skilled man in a technical field. He receives a salary which permits him to bring up his family in a good neighborhood where he is respected as a citizen contributing to the growth of our country.

The electronics technician perhaps lives next door to the industrial electrician. He works under most desirable conditions - often in research laboratories - and contributes in a large way toward the technical progress of our nation. These laboratories must be clean and air conditioned.

The surroundings are pleasant, and his fellow-workers are intelligent and capable. There is usually plenty of work to be done, but he is seldom rushed; moreover, the work is interesting. When the day is over he is not generally weary, as are most of the people doing factory work in our area. The technician is the man we see engaged in civic work or in some pleasant recreation during the evening hours.

14901

PREFACE

This book contains the material taught to the beginning students of the Electronics and Electrical courses in the Camden County Vocational and Technical Schools. After this introduction to Electricity and Electronics, these students continue in their respective trade studies. The following years of course, find them going deeper into the theory of the work that they are then studying.

It is believed that this text will also be found of value in any high school or junior high school teaching electricity or electronics.

There are many people I would like to thank for their help in preparing some of the illustrations, particularly Steve Logeren, a student in the Printing course at this school for the hours he spent in the photographing and offset printing of some of the illustrations.

TABLE OF CONTENTS

PART 1

WELCOME i

PREFACE iii

UNIT I - SAFETY

Lesson 1 Dangerous Hidden Charges 1
2 Safety Practices - 1 4
3 Safety Practices - 2 6
4 Safety in Your Home Workshop 8

UNIT II - TOOLS

Lesson 1 Your Tools 10
2 Care and Use of Your Tools 15
3 Using the Soldering Iron 19

UNIT III - ATOMS, ELECTRONS, AND ELECTRICITY

Lesson 1 Electricity 24
Experiment No. 1 - Static Charges 27
Lesson 2 The Atom 29
3 The Positive Charge 31
Periodic Table of the Elements 32
Lesson 4 Electron Levels 34
5 Atoms, Molecules, and Matter 37

UNIT IV - CURRENT AND CONDUCTORS

Lesson 1 Moving Electrons 39
2 Conductors 41
3 Conductance and Resistance 43
4 Insulators 45
5 Insulators and Conductors (Experiment) 48
6 The Edison Effect 49

UNIT V - VOLTAGE AND POTENTIAL

Lesson 1 Potential 51
2 Electromotive Force 54
3 Electrical Pressure 56
4 Electric Potential (Experiment) 58

UNIT VI - THE BATTERY

Lesson 1 History and Classification 61
2 The Electrolytic Cell 64
3 The Dry Cell 66
4 Secondary Cells 70
5 Batteries in Series and in Parallel 75
6 Batteries in Series-Parallel (Demonstration) 79
7 Charging Batteries 81
8 Other d.c. Sources 83

14903

UNIT VII - RESISTANCE AND RESISTORS

Lesson 1 About Resistors..... 87
2 Resistance in Conductors..... 91
3 Resistance Color Code..... 94
4 Resisting Electrons in a Vacuum Tube..... 98

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson 1 The English and the Metric Systems..... 102
2 Prefixes..... 105
3 Converting From One Unit to Another..... 107
4 Powers of Ten..... 110
5 Negative Exponents..... 112
6 English and Metric Conversions..... 114

UNIT IX - READING THE SCALES

Lesson 1 The Rule and The Yardstick..... 117
2 The Inch Vs. the Centimeter..... 119
3 The Decimal Scales..... 122

UNIT X - THE SLIDE RULE

Lesson 1 Description and History..... 126
2 Logarithms and the Scales..... 128
3 Slide Divisions..... 132
4 Multiplying..... 136
5 Using the Right Index..... 139
6 Placing the Decimal (I)..... 140
7 Placing the Decimal (II)..... 143
8 Dividing (I)..... 145
9 Dividing (II)..... 147

UNIT XI - OHM'S LAW

Lesson 1 George S. Ohm..... 150
2 Resistors in Series..... 153
3 Resistors in Series (Experiment)..... 156
4 Resistors in Parallel..... 158
5 More on Parallel Resistors..... 162
6 Series-Parallel Resistors..... 165
7 Analysis of A Complex Circuit..... 168

UNIT XII - READING THE METERS

Lesson 1 Reading Voltages..... 175
2 Reading Resistance..... 181
3 Measuring Current..... 184
4 The High-Voltage Jack..... 189
5 The High-Current Jack..... 194

ACHIEVEMENT TESTS

UNIT I - SAFETY

Lesson No. I — Dangerous Hidden Charges

"It is better to be safe than sorry." This is so true. The words seem trite, perhaps; and it is possible that to some of you they may be only words. If you will stop and think, it is possible that you know someone who has lost an arm or a hand through a preventable accident. When he came out of the hospital with only one hand he was sorry - real sorry that he had not been just a little more careful.

Always Be Careful

There are many machines in this school which, if misused, may prevent you from every operating any kind of machine. Let us guard our lives, our eyes, our limbs, and our health.

You will be working with voltages at times which are lethal. Lethal is not a bad-sounding word as far as words go, but a lethal voltage can reduce your body to a cinder, can bring sorrow to many members of your family, and can make your loved ones experience the sadness of seeing you lowered into a grave. Lethal means capable of bringing death. REMOVE LETHAL VOLTAGES FROM ALL EQUIPMENT BEFORE MAKING REPAIRS.

Capacitors are incorporated in the circuitry of many pieces of electrical or electronic equipment. These capacitors have the ability to store electrical charges. The equipment may have been removed from the source of voltage for hours and yet remain lethal. These capacitors must be discharged before touching the equipment. This may be done with a shorting bar such as this:

149pg. 00041

Fig. I-1-1

Quite a few men have been killed by capacitor charges. The use of a shorting bar like the one shown could have prevented all of these deaths. The dimensions of the parts will vary with the amount of charge it is designed to short out. The handle may be three or four feet long if it is designed for the man working with high-power radio transmitters or similar electrical equipment.

The large clip on the end of the wire is connected to a good ground connection. Then the curved portion is touched to all parts of the circuit where high voltages could exist.

A smaller or much less elaborate arrangement may be used to discharge potentials in low-power equipment such as communications receivers.

14906

ASSIGNMENT:

1. Is it possible to receive a dangerous electric shock from a piece of electronic or electrical equipment after it is disconnected from its source of electricity?

2. What is the definition of the word lethal?

3. Copy Fig. 1 in your notebook, and give a description of its use.

14907

UNIT I - SAFETY

Lesson No. 2 Safety Practices

Whenever you are working on any electrical equipment make sure you know where the circuit breakers are. Never work around high voltages while alone. If it is necessary to work around high voltages, never use more than one hand. Keep the other hand in your pocket if possible and make sure that you are standing on a good insulating material. Insurance companies and labor unions require that electrical workers stand on rubber mats when working with high voltages.

Wherever you might be working, always know where the fire extinguishers are located. Know how to operate them. A careful worker will even check the inspection tags on the extinguishers to be sure that they have been serviced and inspected according to standards of safety. In school or at work, make sure that you know where you are supposed to go when there is a fire drill. Never use a soda-and-acid extinguisher on an electrical fire. Water, too, should never be used on such fires. On an electrical fire, use a CO_2 (carbon dioxide) extinguisher or some dry type of extinguisher.

It is good policy never to use carbon tetrachloride for cleaning. Breathing fumes from this chemical is much more dangerous than many people suspect. That little amount of poison that you breathe today remains in your body tissues to be added to that which you might breathe tomorrow or next week, and when enough is added to your system, sickness or even death can be the result.

Small cuts and puncture wounds, if not treated, can provide a seat for serious infection.

Use safety belts and every other possible safety precaution if it is necessary to work in high places where you might fall.

14908

When storing equipment on high shelves, be sure that there is plenty of room for it, and that the shelf is strong enough to hold the weight. Do not place anything on a high shelf if there is a possibility that vibration may cause it to fall.

ASSIGNMENT:

1. Why should one never use water to extinguish an electrical fire?

2. Why should one stand on a rubber mat or on something well-insulated from the ground while working with high voltages?

3. Give two reasons why you should know the location of the circuit breakers.

4. Where is the nearest fire extinguisher to your workbench?

5. Where is the next nearest fire extinguisher?

6. Where is the nearest fire-alarm box?

7. What precautions should you take when putting materials on shelves?

14909

UNIT I - SAFETY

Lesson No. 3 Safety Practices-2

The preservation of life is man's greatest instinct. Second only to the preservation of our lives should come the preservation of our sight. Life is difficult enough for those who are born blind, but to become blind after reaching the teens through a preventable accident is sheer tragedy.

Whenever you are using a grinding wheel, a drill press, or doing any work which may result in flying particles capable of causing eye damage, wear goggles or some other type of eye or face guard. One small particle from an ordinary grinding wheel can, in a second, cause the loss of sight.

If you find yourself working in the vicinity of acids or other strong chemicals, you should always wear the goggles recommended to shield your eyes against such chemicals.

You have probably been told never to look at an electric arc or an acetylene arc. This can be extremely dangerous to your vision.

The throwing of any objects in school shops is strictly forbidden. The chance of causing eye damage or loss of sight is greatly increased by such foolish actions. Many types of seemingly harmless horseplay can lead to blindness.

As you grow up, you form habits, and these habits may determine whether or not you are saddled with the miseries of illness in later life. Good posture while working will permit your lungs and other vital organs to perform their work in keeping your body healthy. Never slump while working or studying. Practice good posture. A healthy worker is an alert worker and a safe worker.

MODULAR INSTRUCTION

AUTOMOBILE MECHANICS VOCATIONAL TRAINING

U.S. Reformatory

Petersburg, Virginia

Need for more systematic training and maximum effective use of physical facilities and instructional services has dictated the construction of vocational training and on-the-job training courses comprised of modular instruction and the use of appropriate work or training stations.

Automobile mechanics modular instruction consists of eleven modules comprised of thirty-four performance objectives. Modular course construction allows additions, deletions and revisions to be made with comparative ease. Expansion of certain phases of automobile mechanics, such as brake repair, is simplified by addition of more comprehensive skill and related training in a separate booklet and the addition of a suffix letter to the module number (VII-A).

Module I (Introduction, which contains only one Performance Objective) is included in the form in which all Performance Objective instructions are presented to the trainee. On the left of the booklet are the related studies he must complete prior to beginning the skill training listed on the right. Each sheet is encased in a document protector to avoid grease stains and to prevent tearing of the sheets. Because of the variety of

Loose clothing, necklaces, and fetishes hanging around your neck should never be worn in the shop. This practice is dangerous even if you do most of your work away from moving machinery, because it is easy to forget the danger when going to a machine for a short, unexpected job. Most necklaces are made of metals which are good conductors of electricity. They make excellent electrodes for an electrocution.

The wearing of rings on the fingers can also be dangerous when working around high voltages. Men have been electrocuted by accidently touching their wedding rings to charged wires or components.

So remember: NO NECKLACES AROUND THE NECK. NO RINGS ON THE FINGERS. NO LONG NECKTIES (BOWTIES ARE OK). WEAR SHORT SLEEVES AND NO DANGLING OR LOOSE CLOTHING AROUND MOVING MACHINERY.

ASSIGNMENT:

1. Why would life be more difficult for one who loses his sight in his youth than it is for one who is born blind?

2. Think of three kinds of horseplay that you have seen around school, and then think how blindness could result from such "playing around."

3. What two kinds of dangers arise from the wearing of necklaces around machinery?

4. List all the safety practices included in this lesson.

14911

UNIT I - SAFETY

Lesson No. 4 Safety in Your Home Workshop

If you are truly a student of electricity or of electronics, you will be experimenting at home. You will probably be getting in trouble with your parents for cluttering up your room or the basement or the garage with your wires, transformers, radios, and transmitters. A good student is likely to draw reprimands, especially from his mother, unless he keeps a neat work area at home. You can minimize this if you are neat with your work and if you return all tools to their proper places after using them. Not only will your parents appreciate this, you will be observing one of the most important safety precautions.

A cluttered workbench is an unsafe place to work. On the workbench you should have only the bare necessities to do the job at hand.

Good lighting is also necessary for safe working conditions. If there isn't enough light over your workbench, let the installation of good light be your first project.

Never work on high voltages without someone's being in the room with you - someone who knows where the main switch is and who knows something about first aid in case of electrical shock. If your workshop is on a concrete floor, make sure that you are standing on a rubber mat when working with dangerous voltages. Never work on projects having dangerous voltages after you become sleepy. The 110 volts in your house service can bring death. Even if your shop has a good, dry, hardwood floor, it is still good practice to have a rubber mat upon which to stand.

14912

Regardless of how safe you feel your light switch is, never touch it (or anything else connected to electricity) while in contact with a water pipe, a sink, a spigot, or anything in electrical contact with the ground.

Never work with electricity if you are wet, and use extreme care even if you are slightly damp with perspiration. Stand on a rubber mat, keep one hand in your pocket, and use rubber gloves when possible.

Remember: a great percentage of fatal accidents in this country happen at home.

ASSIGNMENT:

1. Think of three ways one could have an accident working at an overcrowded workbench.

2. How does the returning of tools to their proper places have a bearing on safety?

3. Why is it dangerous practice to touch a light switch while in contact with a water pipe?

4. How does being wet with perspiration add to the danger of working with electricity?

14913 14914

UNIT II - TOOLS

Lesson No. I — Your Tools

The workman who carefully selects and takes pride in his tools is almost always the workman who can be trusted to do a good job. Workmen who do good jobs, of course, are the ones who receive good pay. With an inquiring mind, a sound body, and the proper tools of his trade, a young man beginning the study of his trade is almost assured success.

Would you put up with conditions which would allow rain to get into the gasoline tank of a car, or grit to get into the oil and ruin the bearings? No, you would take better care of a good old jalopy which faithfully carries you around. Would you neglect the simple care required to keep your tools in good shape - the tools which will help you make the money to buy the things you want in life?

If you had a job of tightening screws and were paid according to the number you tightened, would you spend 50 cents more for a screwdriver which would make it possible to tighten five percent more screws each day? Surely, you would. It would not take you long to see that the better tool would mean more money for you. Well, then, would you go to a junk store and buy a cheap soldering iron which would do a job only half as well as a good iron, and take twice as long to do it? You surely wouldn't; that would be false economy. It is possible that the lack of a good soldering iron for just a few days could set a student back far enough to prevent his moving into the next area of achievement, and could make him lose out on a necessary portion of the work of his trade.

There is an old saying about a horseshoe nail. "For the lack of a nail, the shoe was lost. For the lack of the shoe, the horse was lost. For the lack of the horse, the rider was lost. For the lack of the rider, the battle was lost. For the loss of that battle, a kingdom was lost."

It is entirely possible to compare that horseshoe nail with a soldering iron, and that kingdom with your success in life. Buy a good soldering iron. You could, in one evening, throw away more money in a soda shop than the difference in price between a cheap soldering iron and a good one.

There are several good makes to select from. There are the American Beauty, the Unger, and the Weller lines that can be depended upon.

14914

The Unger soldering iron shown here

comes with various sizes and shapes of tips.

This iron is excellent for the work you will be doing in the electronics shop. It is suggested that you get the 47½ - watt tip.

You should also obtain a tool box about the size of a small fishing-tackle box. In fact, tackle boxes make very good tool boxes. Besides the tool box and soldering iron, you will need a roll of rosin-core solder, a 5" or a 6" adustable wrench,

several screwdrivers of assorted sizes,

including a medium and a small Phillips screwdriver,

14915

a pair of 5" long-nose pliers,

a pair of 5" or 6" slip-joint pliers,

a pair of 5" diagonal cutters,

one medium-size file,

one pair of 36" meter test leads, one with a test probe,

the other with an alligator clip—

both with phone tips.

14916

You will need:

2 24" test leads (alligator clips on both ends)

2 36" test leads (alligator clips on both ends)

1 pair of safety goggles

Here is a picture of the tools belonging to a typical freshman in the electronics course.

The student in the electric shop will need a tool kit like the one shown below, containing one each of the following:

6" electrician's side-cutting pliers

6" slip-joint pliers

7" water-pump pliers

5" or 6" long-nose pliers

5" diagonal cutter

Folding carpenter's rule (wood)

Medium screwdriver, approx. 8"

Medium Phillips screw-driver, approx. 7"

Small spirit level

Roll electrician's tape

Roll friction tape

Linesman's tool pouch (the type which attaches to the belt)

Fig. II - 1 - 1

Fig. II - 1 - 2

14918

14917

ASSIGNMENT:

1. Name the tools needed by the electronics students

2. Why does the electrical student need a different method of carrying his tools?

3. Give three reasons for not buying a cheap soldering iron.

4. Why don't skilled craftsmen buy their tools from the so-called bargain stores?

14918

UNIT II - TOOLS

Lesson No. 2 Care and Use of Your Tools

The tool which you will probably use more than any other is the screwdriver, and the tool which is more abused than any other is the screwdriver.

The untrained worker will be found using screwdrivers as chisels, pinchbars, levers, and test probes. You will never see a top-ranking, highly paid workman abusing screwdrivers. The skilled worker is careful with all his tools. He keeps them clean and in good repair. He uses the proper tool for the job, and he returns it to its proper place when the job is finished.

(Some companies will discipline workers found with tools in bad repair - even his own tools and will give such workers "time off" without pay.)

The right size screwdriver must be used. It must fill the slot of the screwhead. If the blade of the screwdriver is too small, it will be hard to keep it in the slot while turning it. In jumping out, the too-small screwdriver will not only damage the screwhead (giving a sloppy appearance to the job), it may also suffer damage itself.

Fig.: II-2-1

If the screwdriver is used as a lever or as a pinchbar, the shank will very often be bent. Once the shank is bent, it is almost impossible to straighten it. Trying to use a screwdriver with a bent shank can lead not only to poor work; serious accidents can result.

14919

When using the screwdriver, make sure that the shank is alined with the axis of the screw; otherwise it may slip from the slot and cause damage.

When it seems that more power is needed to turn the screwdriver, never remedy this by using pliers on the shank. Get a heavier and better-suited screwdriver.

Pliers are made in many sizes and shapes, for many different kinds of jobs. Anything that might change the shape can make them no longer suitable for their intended use. Good pliers are made of good, tempered steel and should never be subjected to heat. High temperatures can ruin the temper, and the steel will become soft.

Never use your delicate long-nose pliers to do a heavy job that calls for gas pliers or perhaps even a wrench. Unskilled workmen have ruined many good pliers in this manner. Do not use pliers as a wrench to tighten or loosen nuts and bolts. Not only will this ruin the milled jaws of the pliers, it will round the corners on the nut or the bolthead.

Your adjustable wrench was not designed for rough service. If extreme force is required to remove a nut or a bolt, you should get an open end wrench.

The adjustable wrench should be kept clean, and the moving parts should have an occasional touch of light oil.

When using a wrench of any type, you should be in a position to pull instead of pushing. If it is necessary to push, do so with caution and apply the force with the palm of your hand. This can prevent hand injuries and bruised knuckles.

Regardless of what kind of wrench you are using, make sure that it fits the nut or bolt that you are turning; and if you are using the adjustable wrench, make sure that you turn it the right way.

14920

automobiles, engines, transmissions and other automotive components, and the variety of test equipment used, it is not feasible to list manuals, charts, test equipment instructions, and other aids needed in performing the skill operations. This requires the student to select pertinent informational materials and to use them as he would in an actual employment situation.

Four areas of related study are utilized although all four are not required for all performance objectives. These areas are: Related Information classes, Programmed Instruction classes, Resource Materials Center, and Trade Theory (Shop Instructor). Related Study has been carefully analyzed to eliminate extraneous materials, thus limiting classroom instruction to the essentials required for efficient skill training of the affected performance objectives. A fifth instructional source is available in Special Education and Remedial classes when a student requires specialized remedial academic instruction to aid him in assimilating related instruction.

Although analysis of related study materials might appear to lessen the teaching load of the related instructors it provides for more individualized instruction for the trainees and provides for greater flexibility in time spent by the trainee in the shop and in the classrooms. Flexibility of movement of students between related classes and the resource materials center is also attained allowing more effective correlation of related subject presentation.

Figure 3 shows the right way to turn the adjustable wrench.

RIGHT DIRECTION

If you turn it in the wrong direction, the wrench can be damaged or can slip off the nut, causing damage to your hand and the job.

WRONG DIRECTION

A poorly ground screwdriver is possibly worse than no screwdriver at all. Study the illustration below and you will see that when it is ground wrong it can easily slip out of the slot. The angle shown here actually would force the blade out of the slot.

SSCI-1

14921

Take pride in your tools. Keep them clean and in good condition. And know where they are.

ASSIGNMENT:

1. Why is it important to turn an adjustable wrench in the proper direction?

2. Give two reasons why you should not use a screwdriver too small for the job.

3. Which can stand more force, the adjustable wrench or the open-end wrench?

4. Why is it that the more highly skilled workers give more care to their tools?

14922

UNIT II - TOOLS

Lesson No. 3 Using the Soldering Iron

Whether you intend to be an electrician,

an electronics technician,

or a radio and TV repairman,

there will be many occasions when you will find it necessary to use a soldering iron.

14923

Practice is needed to attain skill, but there are a few facts with which you must become acquainted first.

The first thing to remember is that the connection to be soldered must be clean. Sometimes a material may look clean but may be covered with an oily or resinous coating which may not be seen by the eye. Steel wool, crocus cloth, a file, or a scratchbrush may be used to clean foreign substances from metal surfaces.

The soldering iron tip must be clean and well tinned. A well-tinned iron is one whose tip is coated with solder and has a clean, silvery appearance. The iron may be cleaned with a dry rag. When the coating of solder is gone, or if the iron has been filed to obtain a smooth tip, it may be retinned. Allow the iron to heat until the bare copper is just beginning to turn color (yellow, brown, or purple) and apply a good rosin-core solder to the tip. This will spread and give the tip a good tinning.

An acid-core solder should never be used on electrical connections. Never use any flux-core solder unless it is rosin-core or one that is recommended by a reputable manufacturer for radio or electrical soldering.

There are three principle types of solder sold in stores supplying the electrical and electronics trade - 40/60, 50/50, and 60/40. Let us look at the first, the most commonly used. This solder is made of a tin-lead alloy containing 40% tin and 60% lead. This is most commonly used because it does a reasonably good job and is less expensive to buy. It will become completely liquid at 460° F.

The 50/50 solder becomes molten at a noticeably lower temperature - 414° F. This solder cost more, however, because it has a greater tin content, and tin is an expensive metal which must be imported from other countries. The 60/40 solder becomes completely liquid at 370° F. This solder is more desirable in most jobs, but, of course, costs still more. The 60/40 solder leaves a shinier job - much neater than the 40/60 solder leaves, but a more important advantage of the 60/40 is that the connection can be soldered at a much lower heat - 90° F. less than with the common 40/60. This is very important because so many components can be ruined by overheating.

A flux is a substance that helps metals form a bond. In the normal wiring jobs that you will be doing, it is not necessary to use any flux other than the flux which is in the core of a good rosin-core solder.

14924

The flux performs two duties. It chemically cleans the surface of oxidations which may escape the eye, and of oily films which might be there from being touched by your fingers. The flux also reduces the surface tension of the molten solder, permitting it to spread and wet like soapy water. This is called wetting. If a soldered connection is properly wetted, the solder has completely covered the entire junction and has run to a thin, feathery edge.

After making sure that both wire and terminal are clean, wrap wire 1 1/2 turns as shown, remembering that the contact must be made between the wire and the terminal - not through the solder. Solder is only for holding. Wrap tightly, and crimp!

Fig. II-3-1

Heat the connection as shown. The soldering iron tip should be against both terminal and wire. Experience will tell you when there is enough heat to make the solder flow properly.

Fig. II-3-2

Some authorities say to apply the solder only to the wire; some say that it may be applied to the tip of the iron and allowed to flow down on the connection. The position of the work will make the difference. If possible, it is best to apply the solder directly to the wire, letting it flow down and around, then feathering out on the terminal.

Fig. II-3-3

14925

The finished job should look like this, with no more solder than is necessary to hold the wire tight on the terminal. Too much solder makes a sloppy job which will get you neither a passing mark in school nor a job in industry.

Fig. II-3-4

It is most important that there be no movement between the wire and the terminal during the time that the molten solder is hardening. If there is movement, a cold-solder joint may result. Most cold-solder joints may be recognized by a dull, powdery appearance, but often cold-solder joints may escape casual inspection. Therefore, it is necessary to carefully examine each soldered connection before accepting it.

Before starting a soldering job it is well to remember the following:

1. Make sure everything the solder is to touch is clean.

2. The soldering tip must be clean and well tinned.

3. Arrange, if possible, for a support to prevent movement while the solder is hardening.

4. Use only enough solder to hold the mechanical connection.

5. Never use an acid-core solder. Use only a rosin flux.

6. Have a dry rag handy to keep the tip clean.

QUESTIONS:

1. What is the percentage of lead in 40/60 solder?

2. What is meant by <u>tinning</u> a soldering-iron tip?

3. Which solder takes a higher temperature to melt, 40/60 or 60/40?

4. What two functions are performed by a flux?

5. What is meant by <u>wetting</u>?

6. In what kinds of electrical wiring jobs is an acid-core solder required?

7. Does a higher tin or a higher lead content in a solder produce the shinier appearance?

14926

BENJAMIN FRANKLIN (1706–1790).

Famous American statesman, scientist, and author; born in Boston; printer and publisher by occupation; made scientific studies in electricity as a diversion rather than as a profession. Introduced the terms positive and negative electricity; proved the identity of lightning and electricity by flying a kite in a thunderstorm; invented the lightning rod; originated the one-fluid theory of electricity.

14927

UNIT III - ATOMS, ELECTRONS, AND ELECTRICITY

Lesson No. I — Electricity

The dictionary tells us that the word electricity is a noun, and comes from the Greek word "elektra," meaning "amber" (a yellowish resin material). Man first produced electricity by rubbing amber. You can see why the name was used.

The first experiences with electricity took place about 600 B.C. The elektra caused some interesting things to happen. For instance, have you ever rubbed a piece of paper against your desk until it stuck, or noticed a quick shock when you touched a door knob in cold, dry weather? Yes, you have shown the same general interest that man has always had in electricity.

More than two thousand years later some men (now called scientists) had formed the habit of examining and organizing their experiences with nature. They learned that the electricity obtained from amber was a "standing" charge. They used the word "static" to describe this charge. ("Static" means standing, still, or stationary. The word "static" was in common use then.) Although the electricity stayed in one place, as on the amber rod, they found that the charge could be transferred to another object, such as a ball made of pith, by touching the ball to the rod.

These early experimentors also found other materials that produced static electricity, such as glass. They also made some mistakes. They had noticed that when a pith ball charged from an amber rod was brought near a pith ball charged from a glass rod, the two attracted each other. Two pith balls charged from the same rod repelled each other.

"UNLIKES" ATTRACT

"LIKES" REPEL

14928

This led them to conclude that there were two different kinds of electricity. The one was called vitreous for glass. Later the word "positive" was used. The other type of electricity was called resinous for the resinous amber rod. Later the word "negative" was used. Despite their error, which you will learn more about in another lesson, the names have stuck - to cause students to have unhappy moments. The experienced person now thinks of positive electricity as merely being less negative. You will see why as you learn more about electricity.

It was in the 19th century that Michael Faraday, the famous English scientist, discovered that the shape of a body has much to do with its holding or releasing a charge. This was just one of his discoveries. Faraday discovered that a hollow metal ball has no removable electrical charge on the inside, and that it has an evenly distributed charge on the outside. He also discovered that if there are points on a charged body, the charge will tend to escape at these points. It is on this principle that spark plugs are designed. Lower voltages may be used on plugs if the electrodes are pointed. (One must realize, however, that the sharper the point, the quicker it will be burned down, effectively widening the gap.)

What seemed to be another kind of electricity was discovered by Count Alessandro Volta, an Italian physicist (1745-1827). This was named voltaic electricity and later came to be known as current electricity. As the word "current" indicates, this electricity involves a flow (or current) of electricity. Currents are produced in various ways: by chemical action in a cell, by movements of a conductor in a magnetic field, by heating the junction of two dissimiliar metals, and by the inductive action of a varying current in one conductor placed near a second conductor.

At this point, let us remember that the word "electricity" is a noun, and that electricity is a form of energy. The word "electric" is an adjective which describes the noun. You never say "Our electric was cut off." The word "electric" is used to describe a motor, a drill, a light, etc.

QUESTIONS:

1. What is the Greek word for amber?

2. How far back in history can the knowledge of electricity be traced?

3. What is the difference between static electricity and voltaic electricity?

14929

14930

4. Early scientists referred to two kinds of electricity, vitreous and resinous. What did they mean?

5. Use the word <u>electric</u> in three different sentences.

6. Use the word <u>electricity</u> in three different sentences.

7. What kind of electricity is that which causes lightening?

14930

As each trainee proceeds through a performance objective in the shop he is guided and assisted by the trainee who immediately preceded him in that operation. This plan provides assistance to the initiate and further training and learning for the student who has completed the objective. This procedure becomes increasingly more valuable as the more complex and intricate performance objectives are reached.

Each instructor, including the shop instructor, records each student's progress in his phase of training on his Training Progress Report (Appendix I) by initialing the block indicating completion of the work required for the appropriate performance objective and module. He then completes the slip referring to his phase of training (Appendix II) and forwards it to the Vocational Training Program Coordinator who is responsible for disseminating this information to the other instructors and for its entry into the trainee's master training record.

UNIT III - ATOMS, ELECTRONS, AND ELECTRICITY

Experiment No. I — Static Charges

OBJECTIVE: To demonstrate static charges.

MATERIAL
- 2 Iron stands
- 2 Pith balls
- 1 Glass rod
- 1 Hard-rubber rod
- 1 Silk cloth
- 1 Wool cloth

PROCEDURE, Part A:

1. Tie a pith ball to each of the iron stands with a light thread about a foot in length.

2. Rub the hard-rubber rod briskly with the wool cloth. (Rod becomes negatively charged.

3. Touch the rod to one of the pith balls. (This will charge the ball negatively.)

4. Rub the glass rod briskly with the silk cloth. (The rod will take on a positive charge.)

5. Touch the glass rod to the other pith ball. (This ball will take on a positive charge.)

6. Bring stands close enough together for the balls to react to each other. (In the above case they will attract each other.)

QUESTIONS:

What happens to the silk cloth when it rubs the glass rod?

What happens to the hard-rubber rod when it is rubbed by the wool cloth?

Give some examples of electrostatic attraction and repulsion that you have seen.

14931 14935

PROCEDURE, Part B:

1. Repeat steps 1, 2, and 3 of the previous procedure.

2. Rub the hard-rubber rod again with the wool cloth.

3. Touch it to the other pith ball. (This ball will also take on a negative charge.)

4. Again place the stands so the balls are close to each other.

5. Observe that the balls will repel one another.

QUESTIONS:

Why do the balls now repel each other?

Give as many examples that you may recall where like charges repel.

14932

UNIT III - ATOMS, ELECTRONS, AND ELECTRICITY

Lesson No. 2 — The Atom

Before you can begin to understand the basic nature of either static or current electricity, you must have some knowledge of the structure of atoms.

All matter is made up of atoms. There are 102 kinds of atoms. Each kind of atom is called an element and has a name. Copper and lead are two examples of elements. There are about twenty elements that you see or use daily. The other elements are a little less common and a few are very rare. Six of the 102 have been made by man from other elements.

Just as all matter is composed of atoms, all atoms are, in turn, made up of three parts: protons, neutrons, and electrons. The different elements just have different amounts of these parts. For electrical purposes we can forget the neutrons. Neutrons are not involved in electricity. However, the protons and electrons are very important. They are electricity.

Fig.: III-2-1
A representation of an atom

The atom looks much like a tiny solar system. These tiny solar systems are so small that thousands of them could be put on the very point of a pin. To be specific, the point of a pin is made up of thousands of atoms. The atoms are so much like small solar systems that some scientists have come to believe that all of nature is made up of different-sized solar systems.

At the center of the atom solar system is a solid part called the nucleus. The nucleus is the heaviest part of the atom, just as the sun is the biggest and heaviest part of our solar system. This is where the protons are. Protons are relatively heavy positively charged particles (solids). Each proton with its single positive charge is tightly bound to the nucleus. This gives us an atom with the positive charge bound in the center.

Whirling around the nucleus as the planets whirl around the sun are the electrons. Each electron carries a negative charge.

14933 14934

215 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

This charge is exactly equal to the positive proton charge but opposite in nature. The electrons are much lighter than protons. Each electron weighs about 1/2000 as much as a proton.

Again like the planets of our solar system, electrons whirl around at various but definite distances from the nucleus. No one can predict exactly where an electron will be during a given instant. But we can predict that a given pair of electrons will stay a certain average distance from the nucleus. While we do not know the reason, we also know that the electrons group in levels. Each level can hold a certain number of electrons, and this number has a great influence on the electrical nature of atoms. A later lesson in this unit will deal with electron distances from the nucleus in more detail.

To summarize: an atom has a heavy, positive central nucleus. Whirling around at various distances from the nucleus are bands or levels of electrons. If it were large enough to be seen, the outer appearance of the atom would be like a little globe.

To get a true appreciation for the atom, you must also understand that electrons of different atoms cannot get any closer than the outermost electrons of each atom. That is, the atoms cannot penetrate each other.

There is a great deal of empty space in an atom. This is just like our solar system, isn't it? Less than 1/10 of one percent of an atom is made up of solid particles. The rest of the atom's volume is empty space. An example will give you an idea of the amount of space. If the nucleus of a "large" atom were the size of a basketball and located in the center of the United States, the outermost electrons would not fit between the Mexican and Canadian borders of the United States!

QUESTIONS:

1. What are all the atoms of one kind called?

2. Name the three parts of an atom.

3. Give your idea of the size of an atom.

4. What kind of electrical charge does the proton have?

5. What kind of charge does the electron have?

6. Where is the proton located?

7. Where are the electrons in an atom?

8. Can you name some elements you come into contact with every day?

14934

UNIT III - ATOMS, ELECTRONS & ELECTRICITY

Lesson No. 3 — The Positive Charge

The last lesson introduced the parts of the atom and mentioned that each element had a different number of those parts.

Through the years scientists have had different views of how the whole pattern of atomic knowledge fits together. The chart on the next page shows the most up-to-date version of that pattern. The chart is organized the way it is because it contains several kinds of information. It is necessary to focus your attention on each point of interest as you go.

First, you will notice that there is a letter symbol in each box. This symbol is an abbreviation for the name of each element (in Greek). For example, H stands for hydrogen and Cu for copper.

Immediately beneath the symbol is a whole number. This is the atomic number of the element. It identifies the element as much as the element's name. The atomic number is the number of protons in the nucleus of the element. This number is always the same for any given element. If you change the number of protons, you have a different element. This different element would have the characteristics of the element of the new atomic number.

Protons cannot be removed or added to an atom by normal electrical means, however. The number of protons can only be changed in an atomic reactor. The process takes an enormous amount of energy.

Thus for practical everyday electrical purposes we cannot move the protons with their positive charges. As a result, we must depend upon the movement of electrons for any practical electrical purpose.

This does not mean that we cannot use a positive charge. The positive charge is always present as a fixed quantity, but in an electrically neutral object, it is exactly balanced by the negative electrons. To get the effect of the positive charge, we need only to remove some of the electrons. Since even a positive electrical charge is generated by moving electrons, it is easier to think of electricity in terms of electrons. Protons are still important. But, since we cannot work with protons for everyday electrical purposes, we ignore them except to appreciate the need for them and their fixed positive charge.

14937

UNIT III - ATOMS, ELECTRONS, & ELECTRICITY

Lesson No. 4 Electron Levels

Atoms are usually neutral. Under normal or ground-state conditions, an atom has one electron for each proton. These electrons are not just lumped together in a solid blob, as you know.

Each electron orbits around the nucleus at some average distance. You might be interested to know that different electrons have different orbital paths. Some are perfectly round and others are elongated, eccentric orbits, coming quite close to the nucleus at one point and going well away at a far point. These orbits use the nucleus to swing around, just as our rockets use the earth and moon to swing around. As a result, they can be just as variable as our rocket orbits.

You should first understand that we still cannot predict exactly where an electron orbit will carry it around the nucleus at a given instant. But by studying optical effects, we can predict probable orbit positions. You may be interested in studying those effects in the future. It is sufficient for now that you know that these same optical effects have convinced scientists that electrons always have an average energy level. For convenience here we will think of all orbits as round, since the shape of the orbit doesn't affect electrical or electronic characteristics.

The electrons of atoms arrange themselves in two patterns. There is a major pattern of seven levels. The electrons of the atom group themselves in one or several bands or shells. These bands are separated by relatively large distances.

Fig. III-4-1

Note that for convenience the circles represent average energy levels and not actual orbits. These narrow shells of widely separated energy levels are numbered 1 through 7, with 1 - the lowest energy level - next to the nucleus and 7 on the outer edge. Of course you realize that not every atom has seven shells of electrons. The

14928

smallest atom, hydrogen, has only one electron, and it is in the first level. Each shell can hold only a certain number of electrons. If an atom has more electrons, they then go into the next shell until all the electrons are in some shell. (Note: An older convention of naming shells uses the letters K through Q instead of the numbers 1 through 7.)

Each shell is in turn divided into sublevels. There are four possible sublevels. These are called s, p, d, and f sublevels. The letters are abbreviations for optical properties caused by the different sublevels.

The first sublevel, the s sublevel, can hold only two electrons. These electrons have the same amount of energy and orbit at the same distance. The s sublevel is the lowest energy level in any shell and it always fills first. The 1 shell has only the s sublevel and can therefore hold only two electrons in all.

The second sublevel is the p sublevel, and it can hold six electrons. Each p electron in this sublevel has the same energy. All p sublevels can hold a maximum of six electrons. The first p sublevel appears in the 2 shell. It is always the second sublevel to fill as each shell gets more electrons. The p sublevel completes the 2 shell, which can therefore hold a total of 8 electrons. Shell 1 is the only shell that cannot have a p sublevel.

The third sublevel is the d sublevel. The d sublevel can hold ten electrons. As is the case with all other sublevels, all the electrons in the sublevel have the same average energy. The d sublevel first appears in the 3 shell, giving a maximum shell size of 18 electrons. The d sublevel can appear in shells 3 through 7.

The fourth sublevel is the f sublevel. The f sublevel can hold 14 electrons. The f sublevel first appears in the fourth shell. It can occur in shells 4 through 7, bringing the maximum of electrons in those shells to 32.

Electron Sublevels
Fig. III-4-2

14939

		6. Remove, Disassemble, Reassemble, Replace, and Test Alternator
		7. Remove, Replace, and Test Voltage Regulator

We are not very concerned with the d and f sublevels, because we cannot readily remove electrons from those sublevels. The s and p sublevels are very important for two reasons. First, these are the electrons that are easily removed or added. These are the electrons that move to provide an electrical current.

The s and p sublevel electrons are also important for another reason. These electrons help determine the nature of the elements. For instance, look at the atomic chart on page 32. You will see true metals in the two left-hand columns. If you look on the right side of each block, you will see a column of numbers; these tell you the number of electrons in each level. The bottom number is the outside level of electrons. All the elements in the first column have one s sublevel electron in the outermost shell. The elements in the second column all have two s sublevel electrons in the outermost shell. A little thought will lead you to the conclusion that s sublevel electrons form metals. If you look around the chart you will find other elements that have only one or two electrons in their outer shells. Yes, these are s sublevel electrons. You will also recognize some of these elements as metals. Except for the first series of elements consisting of only hydrogen and helium, whenever the outer shell of electrons is an s sublevel, the substance is a metal.

Metals are electrical conductors. Non-metallic elements are used to make insulators.

ASSIGNMENT:

1. How does an atom become "charged"? Give an example of both a positive and a negative charge.

2. How many shells of electrons can an atom have?

3. Give the letter for each sublevel.

4. What causes an atom to be a metal?

5. Where do the electrons come from when we have an electric current?

14940

UNIT III - ATOMS, ELECTRONS, AND ELECTRICITY

Lesson No. 5 Atoms, Molecules, and Matter

By this time you know that an atom is made up of a nucleus (the center) and electrons orbiting around this nucleus. These electrons, as you have learned, circle at different distances from the center core (the nucleus). Atoms with many electrons have them circling in a variety of orbits, each a different distance or position from the nucleus. These positions, as you know, are called levels or shells. The copper atom, for example, has four levels.

Fig.: III - 5 - 1 Schematic diagram of an atom of copper

We can see from the diagram that copper has 29 electrons and 29 protons. The atomic number is 29.

All electrons are alike, no matter what kind of atom they might be in. It is the combination of electrons, protons, and neutrons that make a material what it is. The copper atom is actually a sub-microscopic piece of copper. If you put enough copper atoms together, you would have copper with all its characteristics.

If you could read all the 102 symbols on the table of elements, you would not find brass there, or bronze, or steel, or water, salt, or any of countless other substances. These materials are not elements.

14941 14945

Iron is an element. Steel is not. Iron is an element because it can be broken down to its atoms, and each atom will still be iron. Similarly, all the atoms in copper are copper atoms. Steel, on the other hand, is made up of a number of different elements. High-carbon steel is made up principally of iron and carbon. Manganese steel is made of iron, carbon, and manganese, etc. Bronze is made of copper and tin; brass, of copper and zinc. Water consists of hydrogen and oxygen. Common table salt is a combination of sodium and chlorine.

Would you say that water is a mixture of hydrogen and oxygen, or that the salt is a mixture of sodium and chlorine? No. They are compounds. In water, two atoms of hydrogen combine with one atom of oxygen. They don't just rest next to each other; they combine to make a molecule of a substance quite different from either of the combining atoms. This is a compound.

You may mix water, sugar, and lemon juice together and you know what you will get - lemonade. Is lemonade a compound? No, it is a mixture. Here the molecules of the different materials are just resting next to each other. They are not joined together chemically, as are the atoms in compounds.

What are alloys? An alloy is a metal made of two or more other metals mixed together. This is done to get a metal with a different characteristic. Sometimes it is to get a stronger metal, a lighter metal, or one with a lower melting point, like solder. Solder is an alloy of lead and tin. Stainless steel is an alloy of different kinds of steel mixed with chromium. An alloy may be a mixture or it may be a compound.

Alloys usually have greater electrical resistance than any of the individual materials in the mixture or compound. This property is utilized in manufacturing the wire for electrical heating elements. The heating coils in most of our electrical heating applicances are made of nichrome, an alloy of nickel, chromium, and iron.

QUESTIONS:

1. What is an element?

2. What is an alloy?

3. What is a compound?

4. Name three compounds.

5. What is the difference between a compound and a mixture?

14942

UNIT IV - CURRENT AND CONDUCTORS

Lesson No. I — Moving Electrons

By this time you understand that there is constant movement in an atom. The electrons are moving around the nucleus of the atom, in levels or shells. The largest atoms have as many as seven shells.

You will recall that the shell closest to the nucleus is known as the 1 shell; then next to it is the 2 shell, and so on through 7. The first shell cannot have more than two electrons; the second cannot have more than eight; the 3 shell, 18; the 4 shell, 32; and the 5 shell, 32. The number of electrons in the next two shells is uncertain.

If an atom has three shells, the outer shell of that atom may have as many as eighteen electrons. This does not mean that it must have eighteen electrons. Suppose the atom has an atomic number of 13. The 1 shell will have two electrons; the 2 shell will have eight, leaving only three for the 3 shell. Those three electrons are rather loosely held to the nucleus. They are sometimes called free electrons. Certain impulses will cause these electrons to leave the outer shells of their own atoms and enter the outer shells of neighboring atoms. These neighboring atoms, after receiving these electrons, will have too many electrons and will then throw excess electrons on to other atoms.

Impulses such as light, on some materials, strong magnetic fields, or chemical action may set up this condition of exchanging electrons. This is what happens in the conduction of electricity. This action can happen more readily in good conductors than in poor conductors. In the perfect insulator it could not happen at all.

This action of electrons will go down a wire 186,000 miles in one second. Therefore 186,000 miles per second is the speed of electricity. This is also the speed of light.

To help you visualize what happens when a current flows, Figure 1 is a schematic picture of a battery.

14943 14944

You can see that there is a large concentration of electrons around the negative terminal. In fact, there are too many electrons in this area. They are trying to get to that positive area where there is a deficiency of electrons, but they need a good path - a good conductor. A good piece of copper wire will provide that path.

Fig. IV-1-1

If you will connect a piece of wire as shown in Figure 2, the atoms at the negative terminal of the battery will throw some electrons into that end of the wire. This will, of course, begin that chain reaction through the entire length of the wire.

Fig. IV-1-2

This exchange of electrons - all going in the same direction, from negative terminal to positive terminal - is called current flow, electric current, or just plain <u>current</u>.

ASSIGNMENT:

1. How many shells can there be around an atom?

2. What is the speed of electric current?

3. Explain the flow of electric current through a circuit.

4. In which direction do electrons move through a conductor?

14944

UNIT IV - CURRENT AND CONDUCTORS

Lesson No. 2 Conductors

A good conductor (carrier of electric current) is made of a material whose atoms have lots of free electrons.

Copper is the most commonly used material for conductors of electricity. Copper has an atomic number of 29. A copper atom has its electrons in four shells, as shown in Figure IV - 2 - 1.

The first shell has its greatest number of electrons -- 2. The second shell has its greatest number -- 8. The third shell has its greatest number -- 18. The three shells together can hold and do hold 2 + 8 + 18 = 28 electrons.

Fig.: IV-2-1

If the atom of copper has 29 as its atomic number, it has 29 electrons. So, there must be only one electron left for its outermost shell (the 4 shell), which can hold as many as 32 electrons. This one little electron is there, way off by itself, relatively speaking, barely held by the attraction of the nucleus. Just a little attraction from another body will take that electron.

After this electron leaves its orbit, the atom is left in a state of imbalance, and the atom has a positive charge while in this state. It is during the beginning of this action - this sudden change - that this atom will more or less jerk an electron from the outer shell of a neighboring atom.

If you have two conductors of the same material, one with a larger diameter than the other, it stands to reason that the larger

14945 31641

one will carry more current, because it has more atoms and more electrons in it.

The more free electrons a material has, the better conductor that material will be.

Silver has been found to be the best conductor of electricity, and it is used in some applications where only small amounts are needed and where the need outweighs the cost. While silver is the best conductor, copper is the next best. In order of conductivity, conductors run like this:

Silver
Copper
Gold
Aluminum
Tungsten
Zinc
Brass
Platinum
Iron
Nickel
Tin
Steel
Lead
Mercury
Nichrome
Carbon

As previsouly stated, silver is the best conductor, but its cost ordinarily prohibits the use of this metal. Copper is the most practical. Aluminum is a very practical metal, cost-wise, to use as a conductor, but it is only a little more than half as good a conductor as copper. So, taking everything into account, there is nothing like copper as a good, all-around, practical conductor of electricity.

ASSIGNMENT:

1. Must a good conducting material have lots of free electrons or few free electrons?

2. What is the most commonly used material for conductors?

3. What are free electrons?

4. If an atom has lost an electron, does this affect its charge?

5. Which is the better conductor of electricity, silver or copper?

6. Why is copper so universally used as a conductor of electricity?

14946

UNIT IV - CURRENT AND CONDUCTORS

Lesson No. 3 Conductance and Resistance

In all groups, societies, or circles, sooner or later it becomes necessary to compare one thing with another. For this purpose there must be some kind of measurement.

In spite of our civilized approach and our democratic teachings, within a group of boys it is known who is the strongest, the best with his fists, or the smartest. It is usually known that Mike can whip Charlie, but Craig can whip Mike, etc. We might give Mike a rating of 1. On this basis, Charlie might have a rating of 3/4, Craig might rate 1 1/2, and so on.

Since copper is universally used as a conductor of electricity, it is considered as the standard conductor and is assigned the figure 1 for relative conductance. If there were a material twice as good as copper, it would have a relative conductance of 2. If it were only half as good as copper, it would have a relative conductance of 0.5.

Relative conductance is the reciprocal of the relative resistance. The reciprocal of a number is the number 1 divided by that number. For example, the reciprocal of 2 is 1/2; the reciprocal of 10 is 1/10; etc.

Again, copper has the number 1 assigned as its relative resistance. Since the reciprocal of 1 (1 divided by 1) equals 1, therefore we again get the number 1 as copper's relative conductance.

Tests show silver to be only 92% as resistive as copper, making 0.92 the relative resistance of copper. To find the relative conductance, you find the reciprocal of 0.92.

$$\frac{1}{0.92} = 0.92\,\overline{)\,1.00} = 92\,\overline{)\,100.00} = 1.08 \text{ (rel. conductance)}$$

$$\begin{array}{r} 1.08 \\ 92\overline{)\,100.00} \\ \underline{92} \\ 8\,00 \\ 7\,36 \end{array}$$

Therefore, if you take a copper wire of a given size and length and a silver wire of the same size and length, the silver wire will be capable of conducting (carrying) 1.08 times the current that the copper wire will carry.

14847

If you were to use a wire the same size as the copper but made of a material having a relative conductance of 0.75, that wire would carry only three-fourths as much current as the copper wire would carry.

To give you an idea as to how different conductive materials compare, the following table of relative resistances and conductances is given.

Material	Relative Resistance	Relative Conductance
Silver	0.92	1.08
Copper	1.00	1.00
Gold	1.38	0.725
Aluminum	1.59	0.629
Tungsten	3.20	0.312
Zinc	3.62	0.275
Platinum	5.80	0.172
Iron	6.67	0.149
Nickel	7.73	0.129
Tin	8.20	0.121
Steel	8.62	0.116
Lead	12.76	0.081
Nichrome	60.00	0.0166
Carbon	2030.00	0.0004

ASSIGNMENT:

1. Which is the better conductor, zinc or lead?

2. Which material has more resistance, silver or gold?

3. What is the reciprocal of 1? of 3? of 1.59?

4. If a copper conductor will carry 10 amperes, how much current will a nickel conductor of the same size carry when the voltage source and load are the same?

5. Which is the better conductor, zinc or carbon?

14948

UNIT IV - CURRENT AND CONDUCTORS

Lesson No. 4 Insulators

Electrically speaking, materials may be put into two general classes, conductors and insulators.

A conductor must offer little resistance to the flow of electric current. An insulator must offer very, very high resistance to the flow of electric current.

The unit of resistance is the ohm. The perfect conductor would have no resistance - 0 ohms.

The perfect insulator would have extremely high resistance - ∞ ohms. The symbol ∞ means "infinity" - without any limit.

There is no such thing as a perfect conductor or a perfect insulator.

While cost limits us to copper and aluminum for conductors, there are many good insulators. Glass is a very inexpensive material and is an excellent insulator for those situations where glass insulators may be used. The choice of insulators depends on circumstances. In some applications, flexibility ("bendability") may be of great importance. Insulation for hook-up wires and power cords for small applicances fall into this category.

You would want the insulation on the power cord on this drill to last a long time before getting brittle and cracking.

Fig.: IV - 4 - 1

Besides having very high resistance to electric current, there is another quality that is important in an insulator. That property is DIELECTRIC STRENGTH. The dielectric strength of an insulator is its strength against breakdown under electric stress.

14949 14920

IV	Electrical System (Cont.)	8. Remove, Replace, Test, and Adjust Head Lamp Assembly
V	Engine	1. Disassemble, Check, Make Measurements, and Reassemble Engine
		2. Reface Valves and Grind Seats
VI	Cooling System	1. Remove and Replace Radiator, Hoses, Thermostat. Flush Radiator and Engine
		2. Remove and Replace Water Pump
VII	Brake System	1. Remove and Replace Brake Shoes and Overhaul Wheel Cylinder
		2. Overhaul Master Cylinder
VIII	Power Flow	1. Remove, Test, Replace, and Adjust Clutch
		2. Disassemble, Check, and Reassemble Standard Transmission
		3. Remove and Replace Automatic Transmission
		4. Disassemble, Check, and Reassemble Automatic Transmission
		5. Remove Drive Shaft, Remove, Test, and Replace Universal, Replace Shaft
		6. Remove, Disassemble, Check, Reassemble, and Replace Differential

1492

The dielectric strength of the paper insulation between the foil strips in this capacitor must be great enough to retain its insulating properties without breaking down under the voltage applied to it.

Fig.: IV - 4 - 2

Many insulators must possess great strength. The insulators you see holding the long heavy wires on high-voltage transmission lines must be very strong to withstand the weight, wind, ice, and changes in temperature.

Fig.: IV -4 - 3

Electrical insulators are physically classified as solids, liquids, gases, plastics, varnishes, and lacquers. Vacuum, too, is a good insulator and has high dielectric strength.

Insulators are made of molecules with tightly held electrons which are very reluctant to leave their orbits.

14950

ASSIGNMENT:

1. Name as many insulating materials as you can.

2. Into what physical classifications may insulators be put?

3. What is the main difference between a conductor and an insulator?

4. What is meant by <u>dielectric strength</u>?

5. What would happen to a capacitor if the dielectric strength of the insulating material between the plates or strips of foil was too low for the voltage applied?

14951

14951

UNIT IV - CURRENT AND CONDUCTORS

Lesson No. 5
Experiment — Insulators and Conductors

OBJECTIVE: To demonstrate the varying values of resistance found in conductors and nonconductors.

MATERIAL:
1 Ohmmeter with leads
2 Pieces of sheet metal, approximately 2" x 4"
1 Small glass of water
1 Teaspoonful of table salt
1 Blotter
1 Nichrome heating element
1 5' length of copper wire (#22 or #24)

PROCEDURE:

1 - Place dry blotter between the pieces of sheet metal. Connect ohmmeter leads, one to each metal plate. Measure resistance.

2 - Dip the blotter in water and replace between the plates. Again, measure and record resistance.

3 - Dissolve the salt into the water.

4 - Soak the blotter in the salt-water solution, and measure and record the resistance as in steps 1 and 2.

5 - Place the leads to each end of the nichrome heating element. Measure and record resistance.

6 - Replace the nichrome element with 5' length of copper wire and measure the resistance.

QUESTIONS:

1 - After observing the difference in resistance in steps 1 and 4, ask yourself what this tells you about working with electrical circuits when they are wet or damp.

2 - Why is the resistance lower in step 6 than in step 5?

14952

UNIT IV - CURRENT AND CONDUCTORS

Lesson No. 6 — The Edison Effect

When an electric current goes through a conductor, heat is produced. This effect is often used for man's benefit. Usually, however, the heat is not wanted. Great problems have come from excessive heat in electrical and electronic circuits. Before the coming of transistors, there was a heating problem in the design of computers. The many, many vacuum tubes gave off so much heat that the components had to be spaced so far apart that it required several rooms to house some of the early computers.

It was the heating effect of a current that made Thomas Edison's invention of the incandescent lamp possible. "Incandescent" means glowing with light. When a metal approaches 1800° Fahrenheit, it will give off a red light. Thereafter it will become brighter and brighter until it gives off a nearly white light. Edison's problem in the beginning was to keep the wire (the filament) at this high temperature without having it burn up. He found that he had to have it in a vacuum - away from oxygen - so that it would not deteriorate from oxidation (burning). Then he had to find a material which would hold up under the extreme heat.

Edison, America's most celebrated inventor, was also probably the first to observe an electronic effect. One might say that in his discovery of the Edison Effect he had the key to the field of electronics in his hand, but failed to know what was behind the door. He discovered this effect in 1883, just 3 years after he presented the incandescent lamp (the common light bulb) to the world. He constructed a different kind of light bulb this time, in which he placed a small metal plate some distance from the filament. While experimenting with this lamp, he discovered that an electric current would pass between the filament and this little plate. This would happen only when the lamp was burning. Current was actually flowing through space without a visible conductor. This became known as the Edison Effect.

Being a practical inventor, rather than a true scientist, Edison probably left this discovery to give his time and attention to something more practical at that time. More than 17 years later (after the beginning of this century) John A. Fleming, an English electrical engineer, employed Edison's discovery in his creation of the first radio tube. This phenomenon, the Edison Effect, led to the breakthrough into a new field of science. Fleming first used it in his diode vacuum tube to detect radio signals and to rectify alternating current.

14953 14324

Some science writers say that Edison pointed the way to electronics. It is possible that he knew that an entire new world in the use of electricity lay in that direction, but was too busy with problems in another direction to grasp the vast possibilities of that new field.

ASSIGNMENT:

1. Who constructed the first radio tube? For what two purposes was that first tube used?

2. Who discovered that an electric current will pass through a vacuum without a visible conductor? When was this discovery made?

3. If oxygen gets into a light bulb or a vacuum tube, what will happen?

4. What is an incandescent lamp?

5. What was Edison's main problem in developing the incandescent lamp?

6. Can you explain how the Edison Effect made possible a few of the conveniences you now enjoy?

14954

UNIT V - VOLTAGE AND POTENTIAL

Lesson No. I — Potential

Before we talk about potential and voltage, it will be wise for us to review a few of the facts that you have learned about energy. Let us remember that all energy comes from the sun originally - whether it be heat energy, electrical energy, chemical energy, nuclear energy, or mass energy.

The sun's heat may evaporate water from the sea and carry it to higher levels as clouds. Then the water is returned to the earth in the form of rain. Some of this rain may then be stored in lakes. While it is resting in the lake, it has potential energy. The dictionary tells us that "potential" is something that "can be, but has not yet come into being." All this water has potential, potential to turn wheels which, in turn, may perform many thousands of operations. (Of course, you know that energy in motion is kinetic energy.) This stored energy in the lake is potential energy, it can someday do something, but it has not yet done it.

Fig.: V-1-1

If you are sitting under a shelf which has a heavy box poorly placed on the shelf - ready to fall off - the potential is there to put a knot on your head. You could say that there exists a potential danger.

14955

When your father goes to start his automobile in the morning, there must be some kind of potential energy existing to turn the starter. What kind of potential is this? Surely you have already guessed -- CHEMICAL POTENTIAL. There is a potential energy stored in the battery, and this is called chemical energy, or chemical potential.

Let's trace just the high points of the journey of this potential energy from the sun to the automobile battery.

Many millions of years ago the sun supported chemical energy which caused the growth of jungle trees, vines, shrubs, etc. These plants grew, died, and decayed. During the millions of years since, this matter has changed form. It has liquified. It has become liquid petroleum. It is pumped from the ground, and from this material gasoline is made.

It is obvious now that the energy of exploding gasoline turns the motor in the car, making it run. The motor also turns the generator, which charges the battery, converting the rotary motion back into chemical energy. When we use (or discharge) the battery, the chemical energy is converted to electrical energy, which can be used to produce a current. This energy can therefore be called <u>electrical potential</u>.

When you go to the filling station for gasoline, you are concerned about how much gas you are getting. Therefore, there must be a system of measurement. Gasoline and nearly all of our liquids are measured in gallons. When you buy meat, you buy it by the pound. So, just as it is necessary to have a system for measuring gasoline and meat, it is necessary to have a measuring system for potential. Electrical potential is measured in volts.

When one says that a student has the potential to become a great engineer, one means that the student has all the abilities required to

14956

14922

make a good engineer. He "can be, but has not yet come into being."

You have probably heard someone say of a building, "That building is a potential fire trap." He means that everything is favorable for a fire to spread rapidly - lots of rubbish, paper, exposed woodwork, drafty corridors, etc. Fire could race through the building, but one has not yet started. The potential is there.

QUESTIONS:

1 - What is potential energy?

2 - What is kinetic energy?

3 - From what does all energy come originally?

4 - What kind of energy is necessary to turn a starting motor?

5 - Write three sentences using the word "potential."

6 - If a battery has a high potential, does it mean that it is going to do work?

7 - If a student has the potential to become a successful businessman, does it mean that he will become a successful businessman?

14957

UNIT V - VOLTAGE AND POTENTIAL

Lesson No. 2 Electromotive Force

Before talking about electromotive force, it will be best if we first understand potential difference.

Do you remember when you rubbed some of the electrons off the car seat onto the seat of your trousers? What happened? You remember that there was an imbalance created in the atoms of the material in the car seat, and there was an imbalance in the atoms of the material in your clothing. One material had taken some of the electrons from the atoms of the other material. Neither of the materials was left in its original neutral condition. They were both charged - one negatively, and the other positively. There was a difference. We call this difference in charge potential difference. We measure this potential in volts.

When a potential difference exists, there is the potential to return to the original, neutral state. If the potential to change is there, then there must be some kind of force to cause the change. We call this force electromotive force, or e.m.f. Electromotive force, depending on its quantity and rate that it is being expended, is doing most of the work that is being done in the world today. Many other forces are converted to electromotive force before being used. The force of water or of steam is changed to electromotive force in order to distribute it more efficiently and to use it with greater ease.

When you stand by a railroad and see a train being pulled by a diesel-electric engine, you may not realize it, but the wheels are being turned by electromotive force. The mechanical force created by the diesel engine does not drive the wheels directly. Instead the engine drives electric generators, which drive the wheels. This is done because of the increased ease of control and for increased efficiency of fuel.

In the armed forces, there are radio receivers and radio transmitters that are powered by hand-turned generators. Again, this is mechanical force being changed into electromotive force.

There are certain powerful chemicals which have the potential to corrode, burn, eat metal, or to cause change. This chemical energy (this potential to cause change) may be used to produce electromotive

14958

force. This possibility of using chemical energy to produce electromotive force is utilized in the manufacture of batteries - flashlight batteries, radio batteries, automobile batteries, etc.

Electromotive force is measured in volts.

QUESTIONS:

1 - What kind of force drives the wheels of a diesel-electric locomotive?

2 - What kind of force is used to create the force which drives the wheels of the diesel locomotive?

3 - What kind of energy is used to create the electromotive force found in a flashlight battery?

4 - What is potential energy?

5 - In what units of measurement do we measure electromotive force?

14959

1493

UNIT V - VOLTAGE AND POTENTIAL

Lesson No. 3 Electrical Pressure

After becoming familair with potential difference and electromotive force, and after learning just what a volt is, we should now become aware that in the electrical trade electromotive force is referred to as electrical pressure. Sometimes you may hear an electrician refer to e.m.f. as pressure.

When you take another look at electromotive force, it is easy to understand why it may be referred to as pressure. We may use air pressure or water pressure to help us understand electromotive force.

If there is nct enough pressure in the air tank at the filling station, you will never be able to get as much air in your tire as you need.

If there is not enough water in the water tank or standpipe providing the water supply in your community, there will not be enough pressure to send a stream strong enough to wash the mud and dirt off your car.

14960

If you were to have someone, by mistake, put a 6-volt battery in a car which is designed for a 12-volt battery, you are not likely going to take your girl for a ride until you get a battery with enough pressure to crank the motor.

Pressure exerts force, and force does work. Water pressure turns turbines. Air pressure sometimes is used to exert the force needed to run certain small motors and to do various jobs, besides pumping up tires. Some technicians and engineers do not like to use the term pressure when referring to e.m.f. This lesson is not especially designed to encourage you to use this word, but if it helps you to better understand electrical potential, then go ahead and think of it as pressure.

QUESTIONS:

1 - How may you explain electromotive force as pressure?

2 - Give as many examples of pressure as possible, relating each to electromotive force.

14361

4 - Connect as shown below:

Fig.: V-4-2

5 - Close the switch. Is the light now burning as it should be burning? Is the light as bright as it should be? What is the quantity of potential? Why did the lamp not burn before closing the switch? Was there any potential before closing the switch?

14963

An old Baker Electric Automobile actually running on the power of the sun. A battery of solar cells mounted on the top of the car charges the batteries which furnish the power for the car. This car does not pollute the air.

14964

UNIT VI - THE BATTERY

Lesson No. I History and Classification

It is often difficult to find who the real discoverers or inventors were of many of the things that science has given to us, since all inventors build upon the knowledge that others have discovered before them. From about 1725 to the end of that century, many men were working with electricity in their laboratories. In the year 1745, Benjamin Franklin's scientific papers were read at the Royal Society in London. In 1746 and 1747 Franklin was doing experimental work in electricity with Thomas Hopkinson, Philip Syng, and Ebenezer Kinnersley in Philadelphia. In April 1751, a collection of Franklin's papers was published as Experiments and Observations on Electricity. This 80-odd page book made Franklin famous throughout Europe. Just as this great American refused to patent his famous heating stove, wishing others to benefit from his genius, he made public his findings in electrical science. Many scientists in England and all over Europe read his papers, sought his acquaintance, and nearly all benefited from his experiments.

Until the time of Franklin and his contemporaries, the study of electricity had not advanced much beyond man's acquaintance with static charge. This was interesting, but had little practical use. It was in the 18th century that man was to harness and store electricity.

14965 14965

Fig: VI-1-1

The first usable source of electricity was the chemical battery. The process of producing electromotive force by chemical means was discovered by a famous Italian scientist, Luigi Galvani (1737-1798), and the first chemical battery was constructed by another famous Italian, Allesandro Volta (1745-1827). The first chemical battery was known as a voltaic pile.

14966

In 1839, twelve years after the death of Volta, the great French physicist, Georges Leclanché, was born. Most of the batteries that you have handled are based on his invention and are named in his honor. All carbon-zinc dry cells are called Leclanché cells. He was given a patent on this type of cell in 1868 - just three years after the ending of the War Between The States.

Strictly speaking, a battery consists of two or more cells connected together to supply an electric current. The word is also used loosely, however, to mean a single cell that supplies a current.

Batteries are divided into two main groups, primary cells and the secondary cells. The difference between the two groups is that secondary cells are rechargeable, while primary cells are not rechargeable.

The primary-cell group may be divided into three principle classifications: (a) Leclanché cells, (b) alkaline primary cells, and (c) mercury cells.

There are many kinds of secondary cells. Until recently, most secondary cells were wet cells and had to be handled very carefully in order not to spill the electrolyte. The increasing need for rechargeable batteries has caused battery manufacturers to boost research and development to such an extent that we now have two excellent dry secondary cells. These new dry secondary cells are the nickel-cadmium cells and the alkaline secondary cells. Of course they aren't really dry, but are so sealed that they will not spill or leak.

Alkaline cells may be either primary or secondary cells, but you can not recharge the alkaline primary cells.

ASSIGNMENT:

1 - Explain the difference between primary and secondary cells.

2 - Who were Volta and Galvani? When were they born?

3 - What is a Leclanché cell?

14968

14967

UNIT VI - THE BATTERY

Lesson No. 2 — The Electrolytic Cell

Primary and secondary cells work on the same principle. The difference between the types of cells is only one of rechargeability.

A cell works because of the tendency of metals to dissolve in most liquids. For instance, whenever a piece of copper is placed in water it will start to slowly dissolve. This is also true of all other metals, such as iron, lead, and mercury. Some metals, such as sodium, dissolve explosively and would not be satisfactory for manufacturing cells.

The dissolving of metals is a chemical action. Chemical actions are electrical in nature. Thus whenever a given metal is placed in a liquid, such as water, the tendency to dissolve causes a small electromotive force (e.m.f. voltage) between the metal and the liquid. This is an internal e.m.f. We need an external e.m.f., one that will push electrons through a wire.

A usable e.m.f. calls for a different arrangement. Two different metals are placed in a solution that will readily conduct electricity. A solution that will readily conduct electricity is called an electrolyte. Any electrolyte will work, but some electrolytes are better than others for certain metals. A look at Fig. VI-2-1 shows that the electrolyte takes the place of a wire to complete the circuit.

Fig.:VI-2-1

Both metals tend to dissolve in the electrolyte. This causes an internal e.m.f. on each of the metals. Since the metals are different, one e.m.f. is always bigger than the other. A chemist can predict which, but you would have to experiment with a meter. When the two metals are connected by a conductor, as shown in the diagram, the two e.m.f.'s oppose each other. The larger overcomes the smaller. The difference between the e.m.f.'s is the e.m.f. or voltage of the cell. Thus, both metals desire to go into solution, but only the stronger one can do so.

The two metals are called electrodes. One is positive, the other is negative. The electrode that goes into solution is always the negative one. The wires are connected at the terminals of the electrodes. The electrode that dissolves is more negative than the one that doesn't, and that electrode has the negative terminal. The other terminal is less negative and is called the positive terminal, even though it is not really positive.

As the cell is used to produce a current, the negative electrode continues to dissolve. When the terminal is completely dissolved, or when it completely coats the other electrode, the cell is "dead". A primary cell is discarded when dead. With flashlight D cells, the negative electrode is the zinc case and frequently developes leaks before the battery becomes dead.

A secondary cell is recharged with a slightly greater reverse e.m.f. This reverses the chemical process, and the metal of the negative electrode is redeposited during charging until it is back as it was at the start.

QUESTIONS:

1 - What are the 3 essential parts of an electrolytic cell?

2 - What would you say is the basic physical process that makes a cell capable of producing a current?

3 - What makes one electrode the positive terminal, and the other the negative?

4 - What is the negative electrode in an ordinary dry cell?

The following picture shows the structure of a typical dry cell:

Fig.: VI-3-1

14970

COCAI

What we call a dry cell really isn't a dry cell, because the mixture inside is not dry. It must be moist in order to function as a source of electricity. When it is really dry, it is dead.

We also call it a battery, but strictly speaking, it is not a battery. It is a cell. It takes more than one cell to make a battery. The word "battery" means a number of similar articles connected together. This little object which we call a battery is also called a battery by many manufacturers. Many cells are called batteries right on their labels. The label of one declares it to be a "1.5-volt Dry-Cell Battery." So, you are not too wrong if you call it a battery; you are just falling in line with a change in the language. Sometimes these changes are good, sometimes bad. In this case it is not too bad as long as there is no misunderstanding about what you mean.

The 9-volt battery in your transistor radio is a true battery. It is made up of a number of cells which are connected in series and put into a case, with the positive and negative terminals brought to the outside of the battery container.

The common dry cell, like the one shown in the illustration, has a potential of approximately 1.5 volts. Dry cells are electrolytic cells. They produce an e.m.f. as the zinc dissolves in the electrolyte (the pasty material within the cell). As it does so, it leaves some electrons on the zinc case. It is these electrons that produce the current.

The electrons flow to the carbon electrode, where they are removed by chemical action with hydrogen in the electrolyte, resulting in the formation of hydrogen gas.

Dry cells are not rechargeable regardless of the many so-called dry-cell battery chargers on the market. These devices do, however, depolarize the cells (eliminate the hydrogen bubbles from the surface of the carbon electrode). This tends to increase the useful life of the cell.

When the cell is in use, the process called electrolysis is going on inside it, and bubbles of hydrogen are collecting around the carbon electrode. These bubbles are not very good conductors of electricity, so an internal resistance is built up in the battery, making it seem weak or dead.

A depolarizing agent, manganese dioxide, is usually added to the electrolyte to help prevent the formation of bubbles. Time, also, makes a difference. A comparatively new battery which has been polarized through a period of too-long use can sometimes be used again after a rest period. This will give the carbon electrode time to depolarize itself.

14971

These cells are inexpensive to manufacture. This makes them practical for flashlights, portable radios, self-powered model cars and planes, and many other similar applications.

They should not be used for continuous operation or at more than 0.25 amperes. They should never be left in equipment for long periods of time, because after their energy is used up, they sometimes start leaking and exude corrosive chemicals which can ruin the equipment around the battery holder or case. They should never be subjected to high temperatures or stored near steam pipes or heaters.

The word "flashlight" comes from the original, prudent use of the batteries. Flashlights were not originally intended for continuous use. They were intended to be used intermittently (with rest periods). Better design and better materials now make it possible to draw continuous current for longer periods of time. The batteries have to be replaced more often that way, however. Many people are willing to do this if they need the convenience of a continuous light.

ASSIGNMENT:

1 - What are the connection-points on a battery called? What does this word mean? (Study the word in the dictionary.)

2 - Why do batteries sometimes perform better after a rest?

3 - What is meant by <u>depolarization</u>?

4 - What is electrolysis?

5 - Is a flashlight battery really a battery? If not, what is it?

14972

6 - What is the active chemical in the electrolyte of the common dry cell?

7 - Are dry cells considered rechargeable?

8 - Is the carbon rod in the dry cell the positive or the negative electrode?

9 - Of what material is the negative electrode in the dry cell made?

10 - What does the depolarizing agent do in the dry cell?

14973 14974

UNIT VI - THE BATTERY

Lesson No. 4 Secondary Cells

Secondary cells produce an electromotive force, just as primary cells do. The main difference is that secondary cells are rechargeable while primary cells are not. In primary cells, some of the materials are consumed (used up) during discharge. In secondary cells, instead of the materials' being consumed, they are merely exchanged from one part of the cell to another part. The battery may be returned to the charged condition by forcing a current back through the cell in the opposite direction from its discharging direction.

> NOTE: The above statement does not mean that you would connect opposite poles to a battery charger. You connect the +terminal of the charger to (+) on the battery, and the -terminal of the charger to the (-) on the battery in order to charge it. This forces the current into the cell in a direction opposite to that when it was discharging.

Most of us think of an automobile battery when we think of rechargeable secondary cells. Some people even refer to secondary cells as "wet" cells. Actually, there are some secondary cells which look very much like "dry" cells.

14974

The cell shown here, for instance, is a secondary cell which looks like a primary cell. These are very popular now in many small electrical appliances. They can be recharged over and over; and often they have been known to last longer than the appliance itself. They are found in electric toothbrushes, photo-flash units, electric carving knives, electric shavers, electric clothes brushes, etc.

Fig.: VI-4-1

The lead-acid storage battery - the one you see in automobiles - is one of the most widely used batteries at this time because it is capable of providing large quantities of electrical energy. The voltages may be low, but this type of battery is capable of delivering moderate currents for long periods of time and large amounts of current for short periods of time.

Fig.: VI-4-2

Eight flashlight cells will give you approximately the same voltage that you would have in an ordinary 12-volt automobile battery, but will they start an automobile? No. They cannot deliver the current necessary to turn the starter.

The lead-acid cell has, when charged, a potential of approximately 2 volts while under load - slightly more when there is no load on it.

14975

A 6-volt battery has three of these cells connected in series (+terminal to -terminal) like this:

Fig.: VI-4-3

The modern 12-volt automobile battery has six of these 2-volt cells connected in series.

Each cell is made up of numerous lead plates and separators, as shown here.

Fig.: VI-4-4

14976

When the cell is in the charged condition, half of the plates are of lead peroxide (PbO_2) and the other half are composed of sponge lead (Pb). In the charged condition the electrolyte solution consists of pure sulphuric acid in water.

When the cell is in a discharged condition, all of the plates (the positive group and the negative group) contain lead sulphate ($PbSO_4$). Some of the sulphate (SO_4) has left the electrolyte to combine with the lead, and the solution contains less sulphuric acid (H_2SO_4).

Fig.: VI-4-5

When the electrolyte is less acid, it is not as heavy as when it contained more acid. The hydrometer will show this. Some of the solution from the battery is drawn up into it. When the solution is heavy with acid, the float in the hydrometer will rise higher, and when the solution is lighter (the acid content reduced due to discharging) the float will sink lower into the solution. It is in this manner that we can know the condition of a battery by finding the <u>specific gravity</u> of the electrolyte with the hydrometer.

14977

When a discharged lead-acid cell is connected to a battery charger or to a charging generator, the process of electrolysis reverses the chemical action which took place during discharge, and the sulphates (SO_4) are drawn from the plates back into the solution.

The charging and discharging processes may be repeated many times in a good storage battery without wearing out the plates. Before the manufacturers developed better separators, the plates often outlasted the separators. It is important that the battery be kept in the charged condition and that the level of the solution be kept above the tops of the plates.

ASSIGNMENT:

1 - Are automobile batteries made of primary or secondary cells? Why?

2 - Is an ordinary flashlight cell rechargeable?

3 - Is a nickel-cadmium cell a primary or a secondary cell?

4 - Is a carbon-zinc cell a primary or a secondary cell?

5 - What makes up the electrolyte in a lead-acid cell?

6 - What is the approximate voltage of a lead-acid cell?

7 - What are two precautions one may take which will prolong the life of an automobile battery?

14978

UNIT VI - THE BATTERY

Lesson No. 5 — Batteries in Series and in Parallel

You may connect two 1.5-volt penlight cells in series (+ terminal of one to - terminal of the other). Then connect three larger 1.5-volt D-cells in parallel (+ terminals to + terminals, and - terminals to - terminals). Now measure them like this:

Fig.: VI-5-1

If you don't already know what the voltage measurements will be, you are likely to get a surprise. The two little batteries in series will show a greater voltage than will the three larger batteries connected in parallel.

1487021

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: I. INTRODUCTION

MILESTONE: I. INTRODUCTION

PERFORMANCE OBJECTIVE NO.: 1 TITLE: Introduction to Automotive Mechanics

CONDITIONS:

Upon arrival of the trainee, the instructor will approach the trainee and welcome him into the course. A conversation about general topics will be carried on between the instructor and the trainee until the instructor feels that the new man is at ease in the shop environment.

BEHAVIOR:

1. Instructor explains to the trainee the contents and objectives of the course and how it is conducted
2. Instructor explains opportunities of the trade
3. Instructor explains to the trainee what is expected of him and how he is to conduct himself during the course
4. The trainee observes all phases of the training being conducted in the shop

PERFORMANCE CRITERIA:

No performance criteria

When you put cells in series, the voltages are added. When you parallel them - no matter how many - the voltage remains the same as if there were only one cell.

Paralleling the cells is the same as increasing the size. It does not matter how large you make a carbon-zinc cell, the voltage will still be only about 1.5 volts.

The cells shown in the following picture all have the same voltage value. The larger ones, though, can deliver a larger current for a longer period of time than can the smaller ones.

Fig.: VI-5-2

In dry-cell batteries of more than 1.5 volts, there are a number of 1.5-volt cells connected in series. Study this photograph of a 9-volt transistor-radio battery which has been opened so you can see the structure. You can see the little wafer-like cells - six of them.

Fig.: VI-5-3

14980

Even though you can't follow the connections in the photograph, they are connected in series - positive to negative, etc.

Suppose your transistor radio required a higher current than that required by ordinary transistor radios (the larger transistor radios do require more current). You may get this higher current by paralleling two 9-volt batteries. This will give you twice as much current for the same amount of time. If you put three of them in parallel you could draw three times as much current.

Let's assume that you went to the Army Surplus store and bought a piece of surplus electronic equipment which required a working voltage of 18 volts and demanded twice as much current as an ordinary 9-volt transistor radio. How could you combine regular 9-volt batteries to supply this equipment?

You could first put two of the 9-volt batteries in series, making 18 volts. Then you could parallel this series combination with another just like it.

Fig.: VI-5-4

Now you have <u>twice</u> the voltage <u>and</u> <u>twice</u> the current-capability of one battery.

149[illegible]

ASSIGNMENT:

1 - If you connect ten 1.5-volt dry cells in series, how many volts could you measure from the combination?

2 - If you connect twenty 1.5-volt dry cells in parallel, how many volts could you measure from the combination?

3 - If you connect ten cells (1.5-volt carbon-zinc) in series and then parallel them with the ten-cell combination in Question No. 1, how many volts could you measure across the combination?

4 - How do you connect batteries when there is a larger current requirement?

5 - If you had a supply of 1.5-volt carbon-zinc cells capable of sustaining 0.25 amperes, how would you connect them to supply a demand for 6 volts at 1.5 amperes? Draw the diagram.

14982

UNIT VI - THE BATTERY

Lesson No. 6 Demonstration

Batteries in Series-Parallel

OBJECTIVE: To demonstrate voltages obtained from series, parallel, and series-parallel circuits.

EQUIPMENT: 6 No. 6 dry cells

2 Volt-ohmmeter with leads

10 Short-clip leads

1 Potentiometer (1 megohm)

PROCEDURE:

1 - Connect all six cells in parallel. Measure the voltage of this parallel circuit.

2 - Connect three cells in series and the other three in parallel. Measure each arrangement. Now connect the series combination in series with the parallel combination, and measure the voltage across this circuit.

Fig.: VI-6-1

3 - Connect all six cells in series and measure the voltage across the combination.

14[redacted]1

4 - Make connections shown in circuit A. Adjust the variable resistor until the current meter shows maximum current.

(A)

Fig.: VI-6-2

5 - Make the connections shown in circuit B. Adjust the variable resistor until the current meter shows maximum current.

Why is it that the two batteries in (B) will give more current than the three batteries in (A)?

(B)

Fig.: VI-6-3

QUESTIONS:

1 - Do you connect batteries in series or in parallel when you want a higher voltage?

2 - If you need higher current, how may you combine batteries?

149842

UNIT VI - THE BATTERY

Lesson No. 7 — Charging Batteries

You recall that secondary cells may be charged by forcing a current back through the cells in the direction opposite the direction of discharge.

It is done like this.

Fig.: VI-7-1

The motor-generator charger in the diagram could be replaced by a heavy-duty dry-rectifier type, or even by one using vacuum tubes or mercury-vapor tubes. Note the ammeter connected in series with the circuit. This is to show the rate of charge.

It is better to charge a battery at a slow rate (between 5 and 10 amperes). There are many so-called "fast chargers" which may get your battery charged within an hour or two, so that you may continue on your way, but this quick charge can be dangerous to your battery. High currents cause heating, and overheating will often buckle the plates in a battery.

Another precaution you should remember if you ever need to have an automobile battery recharged: NEVER PERMIT ANYONE TO ADD EXTRA ACID TO YOUR BATTERY. This will, of course make the hydrometer show a higher specific gravity reading, but it is a false reading for indicating the condition of your battery. The only time that acid should be added to a battery is if the electrolyte has been spilled out of the battery.

14985

There are little chargers that can be bought for charging nickel-cadmium cells used in small appliances and radios. If you measure the output voltage of these chargers before the battery is connected, the voltage will seem too high, but when the battery is connected, the load of the battery will bring the voltage down to slightly above the rated battery voltage.

The output voltage of a charger, when the battery is connected to the charger, must be slightly more than the battery's voltage. The safe charging voltage for a 6-volt battery is approximately 7.5 volts.

There are numerous kinds of chargers. Perhaps you have heard of the "trickle" charger. You will often see these advertised in the newspapers. A trickle charger is designed to keep stored batteries in a fully charged condition while they are out of service. They are not designed to recharge batteries that are discharged. If you want to buy a charger to recharge an automobile battery, don't buy one unless it can deliver as much as 6 amperes.

A lead-acid battery (your automobile battery) should receive some care. The specific gravity should be occasionally checked and of course, the level of the liquid should always be above the plates. The terminals should be kept clean and properly tightened, so that the battery can receive the charging current from the generator.

Specific gravity is the ratio (comparison) of the weight of something compared with the weight of an equal amount of pure water. The specific gravity of pure water is 1.000. Something with a specific gravity of 1.5 weighs 1.5 times as much as water. The specific gravity of the electrolyte in a charged battery may be between 1.270 and 1.300. If it is ever below 1.200, the battery needs immediate attention.

ASSIGNMENT:

1 - Is it safe to give a fast charge to a battery?

2 - What is the specific gravity of pure water?

3 - Is a lead-acid battery considered charged if the specific gravity is 1.200?

4 - What is the specific garvity of a fully charged automobile battery?

14986

UNIT VI - THE BATTERY

Lesson No. 8 Other D. C. Sources

There are many occasions when d.c. sources are necessary and regular a.c. line voltage will not do the job. A.C. can be changed to d.c., however, in several different ways. You will learn later of several ways to "rectify" a.c. It can also be done by driving a d.c. generator by an a.c. motor. This was shown in the battery charger.

In today's space vehicles there is a great need for d.c. The transmitters and receivers are powered by d.c., and so are many of the instruments used for making hundreds of measurements. The d.c. supply is almost as sophisticated as the vehicles themselves. Fuel cells are used. On present space capsules they are mounted on the outer bulkhead, just behind the astronauts. Electrical energy is obtained as it is needed. This system produces water as a by-product while it is producing energy. The fuel cell seems to meet most of the requirements for space travel so well that some people have suggested them for electric automobiles.

A practical source of d.c. for automobiles is considered very important at this time. Most of us have become so aware of the dangers of air pollution that automobile manufacturers are now making major efforts to produce an electric automobile which will be practical. Pictured here is a 1967 electric model produced in England.

Fig.: VI-8-1

Many people in this country are now employed in research toward producing an electric car that will win the acceptance of the American people. This means that eventually they will attain this goal, and many more electricians and electronics people will be needed in the manufacturing and servicing of these cars.

14987

Here is a picture of the Westinghouse Markette, still in the experimental stage when this picture was taken.

Fig.: VI-8-2

About fifty years ago, an electric car was manufactured in this country. In it were many Edison storage batteries. There were so many that they weighed about as much as the car. Edison cells were expensive, too. There is a lot of nickel in them. The positive electrodes are made of nickel, the negative electrodes are made of iron, and the electrolyte consists of potassium hydroxide and water. The Edison cell has a much longer life than the lead-acid cell, but it does not perform as well at low temperatures.

149001

Vast quantities of alkaline batteries are now being produced for those who want a longer-life disposable battery.

Fig.: VI-8-3

The electrolyte in alkaline batteries is made of alkaline chemicals which are, in a way, the opposite of acids, since they will neutralize each other when combined. Weak alkaline solutions have a slippery feel to the fingers, where an acid solution has a rough feel. Either, if strong enough, can damage the tissues of the body as well as many electrical components if they are carelessly allowed to spill.

Mercury cells are primary cells made for uses where the battery must be smaller than the carbon-zinc type. Modest amounts of current can be drawn from a mercury cell for a longer period of time than can be drawn from a carbon-zinc cell of the same size. Mercury cells also tend to hold their rated voltage longer than other types, instead of gradually tapering off to low voltages.

They come in many sizes and shapes.

Fig.: VI-8-4

A silver-zinc battery has been developed for guided missiles. It has a high power-to-weight ratio, and can be discharged at a higher rate than most conventional batteries. Voltage remains constant during discharge instead of tapering off. This silver-zinc battery is stored in a dry state until time of use and has a very high "shelf" life. It also operates during extreme changes in temperatures, as is necessary for missiles. It is also ideal for emergency use in lifeboats and liferafts carried on aircraft.

ASSIGNMENT:

1 - What is the main advantage of a mercury cell?

2 - Is the mercury cell rechargeable?

3 - Why do people pay higher prices for alkaline cells?

4 - Name two ways one can get d. c. from an a. c. source.

5 - Give two outstanding properties of the silver-zinc cell.

14990

UNIT VII - RESISTANCE AND RESISTORS

Lesson No. 1 About Resistors

George S. Ohm was a German electrician who lived from 1787 to 1854. He found that, when the size or shape of a conductive material was changed, a given voltage would force different amounts of current through the material. He already knew that different materials permitted different amounts of current to pass when the same voltage was applied. So Ohm concluded that the resistance to current flow was determined not only by the kind of material in which it was flowing, but also by the size and shape of the conductor.

There is no such thing as a perfect conductor. All materials have some resistance, even though it might be extremely small.

What is resistance? If your friend decides to take your girl friend to a movie, you will probably say something or commit some act to dissuade him. Whatever you say or do to slow down his budding friendship with your girl can be termed as resistance on your part. If someone tries to do something and someone else does something to prevent it, then he is resisting, or putting up resistance. It is the same with electricity. Resistance can be put into a circuit where it will cut down the flow of electricity - and the more resistance you put there, the less will be the current flow.

There are many instances in electricity and electronics where the flow of electric current needs to be lessened, and in these cases resistors are placed in the lines of current flow.

14991

Resistors come in many sizes and shapes, as you can see in Fig. VII-1-1.

Fig.: VII-1-1

Fig. VII-1-2

Some resistors are of fixed values, and are called <u>fixed resistors</u>. These are fixed resistors.

The symbol for a fixed resistor is drawn like this:

Fig.: VII-1-3

14992

Fig.: VII-1-4

There are adjustable resistors such as this.

The symbol for an adjustable resistor is drawn like this:

Fig.: VII-1-5

Fig.: VII-1-6

There are variable resistors like this. Perhaps you have already seen these resistors and thought of them as volume controls. This type of resistor is used in the volume-control circuits of radios and television sets. These variable resistors may be known as potentiometers or "pots." They may also be used in such a way that they will be called rheostats.

If one is connected in a circuit like this, it will be called a rheostat.

Fig.: VII-1-7

If it is connected in a circuit like this, it will be called a potentiometer or a "pot."

Fig.: VII-1-8

There are large resistors and there are small resistors. The amounts of current and voltage dictate the size. More will be said about this later when we are discussing power.

QUESTIONS:

1 - What is a potentiometer?

2 - How does a rheostat differ from a potentiometer?

3 - In electrical and electronics terms, what is a "pot?"

14994

UNIT VII - RESISTANCE AND RESISTORS

Lesson No. 2 Resistance in Conductors

The ideal wire for conducting electric current would be one without any resistance. As it has been stated before, this is impossible. There is resistance in all conductive materials, and the smaller the size of the wire, the greater will be the resistance.

Wire sizes vary from the fine, hair-like 40-gauge, which is just a little over three one-thousandths of an inch in diameter, up to the large 0000 gauge (four-ought) which is a half inch in diameter. It is obvious that the four-ought gauge would carry large amounts of current, while the resistance of the 40-gauge would be so high that only small amounts of current can pass without burning out the wire.

For measuring wire, the inch is divided into a thousand parts. Each of these parts is called a mil. Therefore, a mil is $\frac{1}{1000}$ inch.

The table on the next page will enable you to compare the characteristics of the different sizes of annealed copper wire. This table will be valuable later when you will be making other comparisons of wire sizes.

14996

Wire gauges are available for measuring unknown sizes of wire. Fig.: VII-2-1 shows a popular gauge found in many electrical and electronics shops. Ask your instructor to let you use one. Get a few known sizes of wire and "get the feel" of the gauge.

Wire gage

Fig.: VII-2-1

QUESTIONS:

1 - How many mils are in a half-inch?

2 - Using the table, find the resistance in 2000 ft. of 24-gauge annealed copper wire.

3 - From the table find the diameter in mils of three-ought wire.

4 - What is the resistance of 5000 ft. of one-ought wire?

5 - What is the resistance of 500 feet of 40-gauge wire?

UNIT VII - RESISTANCE AND RESISTORS

Lesson No. 3 — Resistance Color Code

If manufacturers printed the resistance value on all resistors, it would make it easier for some of us to read them - if they were always in a position where we could see those printed values. Unfortunately, it is not always possible to have them placed in a piece of equipment so that one side of the resistor would always be visible. It has been found that color-coded bands running all around the resistors make it much easier to read their values when they are in close places. Color-coding is very helpful in trouble-shooting, since locating certain resistors can save time in locating a particular area in a circuit.

Most resistors have four bands around them. Some have only three. Starting from one end of the resistor, the first band indicates the first "significant figure" in the resistance value of that resistor. (The first significant figure means the first figure, so long as it is not an initial zero following a decimal point. For example the first significant figure in the number .078 is 7.)

RESISTOR COLOR CODE

Fig.: VII-3-1

The second band represents the second significant figure and the third band tells us by what number to multiply the first two figures to obtain the total value of resistance of that resistor. The fourth band lets us know the tolerance of the resistor.

Let us study the tolerance band first. You will note in the color-code table (page 95) that if the fourth band is of gold, the tolerance is 5%. That means that if, for example, it is a 100-ohm resistor, its resistance can range between 95 ohms and 105 ohms and still be considered acceptable.

If you need a 100-ohm resistor "five-percenter" and go to the radio-supply store and tell the man behind the counter that that is what you want, he will give you one with a brown, black, brown, gold set of color bands on it. The gold band (the fourth band) tells you that this resistor has a 5% tolerance. If, when you get home, you measure the value of this resistance with your ohmmeter

14998

and find that it is only 95 ohms, don't think that you were given the wrong resistor. The resistor is within 5%, since 95 ohms is 95% of 100. It could have been 105 ohms, and you would still have a "five-percenter."

If, instead of a gold band, you had a silver band for tolerance, the 100-ohm resistor could be anywhere between 90 and 110 ohms and still be within the tolerance range. If there is no tolerance band on the resistor, it is a "twenty-percenter" - that is, its actual resistance could be anywhere between 80 ohms and 120 ohms.

Some electrical circuits require components of very close tolerances if the circuit is to operate properly. There are other electrical circuits where the tolerances are not as close. When the tolerances are not too close, we can use resistors with 10% and even 20% tolerances. Circuits such as those that are not too critical can be manufactured at less expense than those of close tolerances. It is more costly for the manufacturers of resistors to test and sort five-percenters than twenty-percenters; therefore the five-percenters must sell for a higher price.

Study the Resistor Color-Code table, and you will be able to understand how a resistor color-coded RED RED RED GOLD would be read 2200 ohms + 5%. The first band, being red, tells you that the first figure is a 2. The next band, being red, tells you that the second figure is another 2. The third band (the multiplier band), being red, tells you that the first and second figures are to be multiplied by 100. So, you have 22 X 100 = 2200

Color	1st Digit	2nd Digit	Multiplier	Tolerance (Percent)
Black	0	0	1	
Brown	1	1	10

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: II. TOOLS

MILESTONE: I. TOOL IDENTIFICATION AND USE

PERFORMANCE OBJECTIVE NO.: 1 TITLE: Identification and Use of Tools

CONDITIONS:

Student will be provided the opportunity to open racks and study tools under the supervision of the shop instructor. The teaching machine is available for use by the student when and where necessary.

BEHAVIOR:

After the satisfactory completion of all related studies:

1. Tool modules should be run on the teaching machine
2. Open tool board and identify each tool, its use and proper method of use
3. Repeat steps #1 and #2 until you can identify all tools and their use

PERFORMANCE CRITERIA:

To be able to identify all automobile mechanics tools.

Learning time: 3 hours

QUESTIONS:

What are the resistance values of the resistors color-coded as follows:

1.	WHITE	BLACK	ORANGE	GOLD
2.	BROWN	WHITE	RED	GOLD
3.	GREEN	ORANGE	ORANGE	
4.	GRAY	BLACK	BLACK	SILVER
5.	BROWN	BROWN	BROWN	GOLD
6.	BLUE	YELLOW	YELLOW	
7.	VIOLET	YELLOW	RED	
8.	GREEN	RED	ORANGE	SILVER
9.	GRAY	ORANGE	ORANGE	GOLD
10.	RED	RED	RED

UNIT VII - RESISTANCE AND RESISTORS

Lesson No. 4 — Resisting Electrons in a Vacuum Tube

It does not matter whether little Mike is pulling back on the wagon or pushing back from the front, he is still resisting Bobby's effort to pull the wagon forward.

15002

To "resist" is to oppose, to hinder, to check, to hold back, or to obstruct. To "repel" is to push back, drive away, oppose. Anything that opposes or repels the flow of an electric current may be considered as resistance.

Let us look at the diagram of a vacuum tube - a simple triode vacuum tube.

Fig.: VII-4-1

When the filament (called "cathode" in the diagram) is heated, it will emit (or boil off) electrons. A positive charge on the plate will attract them, causing a current to flow. If, however, a negative charge is put on the grid which is placed between the filament and the plate (the "anode"), the negatively charged electrons will be repelled by this negative charge. REMEMBER, ELECTRONS ARE ALWAYS NEGATIVELY CHARGED. THERE IS NO SUCH THING AS A POSITIVE ELECTRON.

The higher the negative charge is on the grid, the smaller the current will be. All tubes have a cut-off point, at which the flow of current between the cathode and the plate will stop.

If you will study the following curve, you will see that increasing the negative charge on the grid of a vacuum tube gradually cuts down the flow of current until it is completely cut off.

15003

216 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

Look at the curve and you will see that, with no potential on the grid, four milliamperes of current will flow. If a negative charge of 1 volt is applied to the grid, only about two milliamperes will flow. When -5 volts is on the grid, the current is completely cut off. This curve is called a characteristic curve. All tube types have characteristic curves which may be referred to in designing electronic circuits.

QUESTIONS:

1 - Define resistance, giving three different kinds of resistance.

2 - If current is to flow in a vacuum tube, at what polarity must the plate be? And at what potential must the cathode be?

3 - Which element in the vacuum tube is the anode?

4 - If a tube has only a filament, a grid, and a plate, which of these electrodes is the cathode?

5 - In your notebook, draw the diagram of a triode vacuum tube and label each electrode.

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson No. 1 The English and the Metric Systems

Can you imagine how your ancestors measured distance, weight, and volume 10,000 years ago? Well, if the distance happened to be ten or twelve miles, he probably called it a day's walk - that is, if he lived on flat land. Had he been in mountainous country, he probably would have called it a three or four-day journey, depending on the ruggedness of the land. Firewood was probably measured by the armful - and this would vary from man to man, depending on how long his arms were. You can use your imagination and perhaps guess what units he used for weight.

During the years covered by biblical writings there was a standard of length called the cubit. There was also a measurement called Ezekiel's reed, which was supposed to have been six cubits. Another unit was called a schaenus. For many hundreds of years, while man was becoming more and more civilized, he did not have a practical system of measurement.

The first successful effort to standardize a system of weights and measurements was made by the English in 1266, just a little more than 200 years before Columbus made his famous voyage to America.

In the English system, the yard is used as the standard unit of length, while the pound is the standard unit of weight. In spite of the difficulties of dealing with numbers like 36 and 16, and the awkward fractions that result, we still use some of that system in our country.

Over 500 years after the adoption of the English system, the National Assembly of France proposed, in 1793, a much more convenient system, the metric system, which they made legal six years later. Since then, most of the advanced countries of the world have adopted the metric system; in this country we use it in our scientific work. It is called the metric system because the unit of length is the meter.

The unit of weight, in the metric system, is the gram. Heavy objects are weighed in kilograms, and very light objects, in milligrams. We can convert (change) grams to kilograms or milligrams merely by moving the decimal. This is impossible in the English system.

15006

1 kilogram = 1000 grams

1 centigram = 0.01 gram

1 milligram = 0.001 gram

Can you do this with ounces, pounds, tons, etc.?

The meter is the basic unit of length in the metric system. One kilometer is one thousand meters, and one millimeter is 1/1000 of a meter. You may know that in France and in numerous other European countries, speedometers in cars are read in kilometers instead of miles.

Let's look at a meter stick. Perhaps you have seen one and thought that it was a yard stick. If you will compare one with a yardstick, you will see that the meter stick is a little longer than the yard stick. In fact, it is 3.37 inches longer. Let's look at that meter stick again and visualize a thousand of them lying end-to-end. That distance would be one kilometer.

KILO MEANS ONE THOUSAND

If you don't have a gram, a kilogram, and a milligram weight, send someone to the chemistry or the physics department in your school to borrow one of each and compare them. Hold the gram weight in one hand and the kilogram weight in the other. Remember that the kilogram weight is a thousand times as heavy as the gram weight. You may have trouble finding a milligram weight, but probably you will be able to locate a 50-milligram weight. With that you will be able to understand that a milligram is a thousand times lighter than the gram. So let us remember that, in the metric system,

MILLI MEANS ONE THOUSANDTH

QUESTIONS:

1 - What is the unit of weight in the English system?

2 - How long ago was the English system devised?

3 - What is the unit of weight in the metric system?

15007

4 - Where did the metric system get its name?

5 - What is the unit of length in the metric system?

6 - What is the unit of length in the English system?

7 - What does kilo mean?

8 - What does milli mean?

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson No. 2 — Prefixes

You have learned that kilo means one thousand times the unit and that milli means one thousandth (1/1000) of the unit. Now, what part of a dollar is a cent? Of course you know that it is one hundredth. So it is reasonable to assume that a centigram is one hundredth (1/100) of a gram. Also, you should recognize that 1/100 of a gram may be written .01 gram or, better, 0.01 gram.

There will be many occasions when you will be expected to know the metric units of weight and length during your career in electricity or electronics. So get a good start today and learn these two simple tables.

1 millimeter	=	0.001 meter	=	1/1000	meter
1 centimeter	=	0.01 meter	=	1/100	meter
1 decimeter	=	0.1 meter	=	1/10	meter
1 decameter	=	10 meters			
1 hectometer	=	100 meters			
1 kilometer	=	1000 meters			

1 milligram	=	0.001 gram	=	1/1000	gram
1 centigram	=	0.01 gram	=	1/100	gram
1 decigram	=	0.1 gram	=	1/10	gram
1 decagram	=	10 grams			
1 hectogram	=	100 grams			
1 kilogram	=	1000 grams			

You now have prefixes from thousandths to thousands. There are two other prefixes you should learn at this time. They are meg or mega and micro. Meg or mega indicates one million, while micro means one millionth.

Resistance is often measured in millions of ohms, or megohms. Capacitance is often measured in millionths of farads, or microfarads. Capacitance is even measured millionths of millionths, or micromicrofarads. You will also see a relatively new term - pico - used for micromicro. A micromicrofarad (one millionth of a millionth of a farad) may be called a picofarad.

15009 C1021

You can see now, with science and technologies growing each day, that we can find new ways to help ease the burdens in learning and working. So scientists asked, "Why use a word a block long when a short word will do just as well?" So we have pico instead of micro-micro.

If you will look at the table you will see that there are a thousand millimeters in a meter. That must be so, must it not, since 1 millimeter equals 0.001 meter or 1/1000 of a meter.

How many millimeters, then, would there be in a centimeter? Look at the decimal fractions 0.001, 0.01, and 0.1. Each time the decimal is moved one space to the right, you are multiplying by 10. One millimeter equals 0.001 meter, while one centimeter equals 0.01 meter. We get the centimeter length by multiplying the millimeter length by 10. So, there must be 10 millimeters in a centimeter. Again, there will be 10 centimeters in a decimeter and 10 decimeters in a meter, making 10 x 10 x 10 or 1000 millimeters in a meter.

QUESTIONS:

1 - How many centimeters are there in a decameter?

2 - How many centimeters are there in a meter?

3 - How many milligrams are there in a gram?

4 - How many centigrams are there in a decigram?

5 - How many grams are there in a kilogram?

6 - How many millimeters are there in a meter?

7 - How many picofarads are there in a farad?

8 - How many ohms are there in a megohm?

9 - How many microfarads are there in a farad?

10 - How many micromicrofarads are there in a farad?

15010

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson No. 3 — Converting from One Unit to Another

If you want to tell someone the weight of a package that contains 50 4-ounce switches, you do not tell him it will weigh 200 ounces. You tell him it will weigh 12 1/2 pounds. You converted the number of ounces to pounds by dividing:

$$\frac{\text{number of ounces}}{16} = \text{number of pounds}$$

$$\frac{200 \text{ ounces}}{16} = 12\ 1/2 \text{ pounds}$$

Converting from one unit to another in the metric system is much easier, since any unit may be changed to any other merely by moving the decimal point.

Move the decimal point to the right to multiply; move the decimal point to the left to divide.

Move the decimal point one place to multiply or divide by 10; 2 places, by 100; 3 places, by 1000, etc.

For example, to change 2.43 centimeters to millimeters, we must multiply 2.43 by 10 (since there are 10 millimeters in a centimeter). We do this very simply by moving the decimal point one place to the right.

2.43 cm. x 10 = 24.3 mm.

Suppose we wish to change 256 centimeters to meters. We must divide by 100, since there are 100 centimeters to a meter.

Where is the decimal point in the number 256? There is none. But we know that when there is no decimal point in a number, we can understand a decimal point as coming after the number.

256 = 256.

15011

Therefore to divide 256 by 100, we move the "understood" decimal point two places to the left.

256. ÷ 100 = 2.56

256 centimeters = 2.56 meters

Let us change 24 milligrams to centigrams. We must move the decimal point one place to the left in order to divide by 10. We understand the decimal point to be to the right of the number.

24 mg. = 24. mg.

24. ÷ 10 = 2.4 centigrams

Students sometimes are puzzled as to whether to divide or multiply when converting one unit to another. If you have a large unit (like miles or kilometers) to change to a small unit (like yards or meters), you multiply. You need to end up with <u>more</u> of the small unit than of the large unit.

No. of miles x 1760 = No. of yards.

5 miles x 1760 = 8800 yards

No. of kilometers x 1000 = No. of meters

5 kilometers x 1000 = 5000 meters

Conversely, to change from a small unit to a large unit, you want to end up with a <u>smaller</u> amount of the large unit, so you divide.

No. of ounces ÷ 16 = No. of pounds

200 ounces ÷ 16 = 12 1/2 pounds

No. of centigrams ÷ 100 = No. of grams

500 centigrams ÷ 100 = 5 grams

How many meters in 45 centimeters? We must divide by 100. Understanding the decimal point to be after the number, we move it

15012

two places to the left and get 0.45 meters.

How many meters in 45 millimeters? We need to move the decimal point three places to the left.

But there are only two places to the number. So we must indicate the third place by a zero. We get

45 mm. ÷ 1000 = .045 meters

How many milligrams are there in 8 grams? Here again, we will have to add zeros.

8 grams = 8. grams

8. x 1000 = 8000 milligrams

Show how 2.5 kilometers equals 2500 meters.
Show how 68 milligrams equals .068 grams.
Show how .79 kilometers equals 790 meters.
Show how 800 centimeters equals 8 meters.

QUESTIONS:

1 - Express the following numbers in centimeters:
1 meter 3.5 meters 257 meters .5 meters
3000 millimeters 250 millimeters 10 millimeters
.06 meters 6795 millimeters .265 meters 1 kilometer

2 - Express the following numbers in meters:
1 kilometer 27 kilometers 200 centimeters 56 centimeters
265 millimeters .098 kilometers 3657 centimeters
20 kilometers 2987 millimeters 42.5 centimeters .5 kilometers

3 - Express the following numbers in milligrams:
1 gram 8.7 grams 200 grams .054 grams
65 centigrams 18 centigrams 2.9 centigrams 300 centigrams
10 grams .398 grams .016 grams .0025 centigrams

4 - Express the following numbers in grams:
10 centigrams 367 milligrams 2400 centigrams 7.5 centigrams
1 kilogram 590 centigrams 20,000 milligrams 30 kilograms

5 - Can you think of any system of measures in our country that uses a decimal system to convert from one unit to another?

15013

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson No. 4 — Powers of Ten

Isn't it a lot easier to write 10^6 than to write 1,000,000? Well 10^6 is 1,000,000. That little 6 standing to the right and above the 10 is called an <u>exponent</u> or a <u>power</u> of ten. It is like the 2 in 10^2 meaning 10 x 10 and the 3 in 10^3 meaning 10 x 10 x 10. When we write 10^6 it means 10 x 10 x 10 x 10 x 10 x 10 or 1,000,000. Not only is it easier to write large numbers this way, it is easier to multiply and divide when we write them in this way.

Suppose you wish to multiply a million by a million. Until now you probably did it like this, by adding 6 zeros to 1,000,000.

$$\begin{array}{r} 1{,}000{,}000 \\ \times \quad 1{,}000{,}000 \\ \hline 1{,}000{,}000{,}000{,}000 \end{array}$$

It is much easier to do it this way:

$$10^6 \times 10^6 = 10^{12}$$

10^{12} is a million million. You will notice that the multiplication was done by merely <u>adding</u> the exponents. 10^{12} means 1 with twelve zeros to the right.

10^2 = 100 (1 with two zeros to the right)

10^3 = 1,000 (1 with three zeros to the right)

10^9 = 1,000,000,000 (1 with nine zeros to the right)

Suppose we have to multiply a billion by a thousand

1,000,000,000 x 1,000 = $10^9 \times 10^3 = 10^{12}$ or 1,000,000,000,000.

You can certainly see that it is much easier to give the answer as 10^{12}.

15013
15014

Powe s of ten are a kind of shorthand for mathematics.

Let's look at these multiplications:

$40{,}000 = 4 \times 10^4$

$40{,}000 \times 300{,}000 = 4 \times 10^4 \times 3 \times 10^5 = 12 \times 10^9$

$15{,}000{,}000 = 15 \times 10^6$ or 1.5×10^7

$360{,}000 = 3.6 \times 10^5$

$19{,}000{,}000 \times 42{,}000 = 1.9 \times 10^7 \times 4.2 \times 10^4 = 7.98 \times 10^{11}$

ASSIGNMENT:

Multiply

1. $6 \times 10^6 \times 2 \times 10^3$
2. $3 \times 10^3 \times 1 \times 10^4$
3. $1 \times 10^6 \times 12 \times 10^6$
4. $2.5 \times 10^3 \times 4 \times 10^{11}$
5. $18 \times 10^4 \times 2 \times 10^7$
6. $5 \times 10^3 \times 3 \times 10^8$
7. $6 \times 10^3 \times 2.5 \times 10^6$
8. $8 \times 10^2 \times 3 \times 10^{14}$
9. $15 \times 10^9 \times 2 \times 10^4$
10. $50 \times 10^3 \times 0.5 \times 10^3$

Express as powers of 10 and multiply

11. 17,000 x 2,000,000
12. 300,000 x 240,000
13. 780,000 x 30,000,000
14. 40,000 x 160,000
15. 35,000,000 x 290,000

15015

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson No. 5 — Negative Exponents

You know that $10^3 = 1{,}000$. What would you think 10^{-3} would be? Suppose you look at the following little table.

10^{-3}	=	0.001	=	1/1,000
10^{-2}	=	0.01	=	1/100
10^{-1}	=	0.1	=	1/10
10^{0}	=	1		
10^{1}	=	10		
10^{2}	=	100		
10^{3}	=	1,000		

This table shows you that when the exponent has a negative sign in front of it the number is <u>less</u> than <u>one</u>, and the <u>larger</u> that negative exponent, the <u>smaller</u> a part of one it will be.

Let's examine a few examples involving numbers which are all <u>less than one</u>.

$2 \times 10^{-3} = 2 \times 0.001 = 0.002$

$2 \times 10^{-3} \times 4 \times 10^{-3} = 8 \times 10^{-6} = 8 \times 0.000001 = 0.000008$

$3 \times 10^{-2} \times 2 \times 10^{-1} = 6 \times 10^{-3} = 6 \times 0.001 = 0.006$

IT IS IMPORTANT THAT YOU REMEMBER THAT WHEN A NUMBER STANDS ALONE WITH NO DECIMAL EITHER IN FRONT OR IN BACK OF IT, IT IS UNDERSTOOD THAT THERE IS A DECIMAL IN THE BACK OF IT - THAT IS, TO THE RIGHT.

This (6) is the same as this (6.)

15016

Now if you want to express 6×10^{-3} in decimal equivalent, you start from the decimal, which you know is to the right of the 6, and count three places to the left:

0.006

and show it in this manner. Of course, you read it as six one-thousandths, or simply six thousandths.

One more thing. Suppose you had to add -2 to +5? You know from algebra that -2 +5 = + 3. Similarly, +6 + (-4) = +2.

If you are multiplying negative and positive powers of 10, the exponents need only to be added algebraically.

$10^{-2} \times 10^{-5} = 10^{-7}$

$10^{-5} \times 10^{3} = 10^{-2}$

$3 \times 10^{-2} \times 2 \times 10^{6} = 6 \times 10^{4}$

$3 \times 10^{-4} \times 3 \times 10^{18} = 9 \times 10^{14}$

$2 \times 10^{-3} \times 2 \times 10^{9} = 4 \times 10^{6}$

$4 \times 10^{-12} \times 3 \times 10^{3} = 12 \times 10^{-9}$

$2 \times 10^{-4} \times 3 \times 10^{6} \times 10^{-12} \times 3 \times 10^{4} = 18 \times 10^{-6}$

ASSIGNMENT:

Multiply

1. $2 \times 10^{3} \times 2 \times 10^{-3}$
2. $3 \times 10^{4} \times 2 \times 10^{-9}$
3. $4 \times 10^{2} \times 2.5 \times 10^{-8}$
4. $5 \times 10^{-9} \times 2 \times 10^{6}$
5. $1.5 \times 10^{3} \times 4 \times 10^{-9}$
6. $25 \times 10^{-12} \times 3 \times 10^{6}$
7. $19 \times 10^{8} \times 1 \times 10^{-3}$
8. $9 \times 10^{12} \times 3 \times 10^{-5}$
9. $6 \times 10^{-15} \times 6 \times 10^{12}$

81021 15017

UNIT VIII - THE METRIC SYSTEM AND POWERS OF TEN

Lesson No. 6 — English and Metric Conversions

There are many occasions when you will find it necessary to convert from one system of measurements to the other. Suppose you bought a European automobile whose nuts and bolts were made according to metric measurements, and you wanted to know how many inches the metric measurements came to. Suppose you happened to be visiting in some European country and wanted to buy some cloth to send to the girl friend so she could make a dress. If you asked for five yards of the material, the man behind the counter might ask you how many meters there are in your yard. This happened to the author of this book in a department store in a small town in Portugal.

Not only is it a nice thing to be able to know the relationships and to be able to make the conversions, but it is necessary that you, going into the electrical or the electronics trade, be able to convert from one system to the other. Study the following table of comparisons and conversions.

1 foot	=	0.3048 meters
1 foot, cubic	=	0.0283 cubic meters
1 foot, square	=	0.0929 square meters
1 inch	=	0.0254 meters
1 inch	=	2.54 centimeters
1 mile	=	1.6093 kilometers
1 pint, liquid	=	0.4732 liters
1 pound	=	0.4536 kilograms
1 yard	=	0.9144 meters
1 yard, cubic	=	0.7646 cubic meters
1 yard, square	=	0.8361 square meters

15018

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: III. FUEL SYSTEM

MILESTONE: I. FUEL PUMP

PERFORMANCE OBJECTIVE NO.: 1 TITLE: Remove, Overhaul, Replace, and Test Fuel Pump

CONDITIONS:

Assignment will be performed on complete automobile

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective cover on front seat of automobile
2. Move automobile into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper tools and materials
6. Select proper manual and turn to appropiate chapter
7. Disconnect fuel line and any other attached accesories
8. Remove fuel tank cap and blow fuel from line to prevent siphoning
9. Remove attaching bolts from pump
10. Remove pump from engine and place on work bench
11. Disassemble pump following steps as outlined in manual
12. Identify all parts of the pump and the function of each
13. Reassemble the pump following steps as outlined in the manual

PERFORMANCE CRITERIA:

1499

1 centimeter	=	0.3937 inches
1 gram	=	0.0353 ounces
1 kilogram	=	2.2046 pounds
1 kilometer	=	0.6214 miles
1 liter	=	2.1134 liquid pints
1 meter	=	3.2808 feet
1 meter	=	39.37 inches
1 meter	=	1.0936 yards

Just for fun, let's imagine that you were visiting a friend in Argentina and wanted to help him out by doing a job for him. In the Argentine, the peso is the unit of money; and there are 100 centavos in a peso just as we have 100 cents in our dollar. Suppose that, at the present exchange rate, one American dollar is worth four Argentine pesos, and you wish to buy 250 feet of insulated wire from a store in Buenos Aires. The price there is 12.5 centavos per meter. How much American money would you have to pay for the 250 feet of wire?

From the table find that 1 ft. = 0.3048 meter

You need 250 X 0.3048 = 76.2 meters of wire

76.2 X 0.125 = 9.525 (nine pesos and fifty-two and half centavos)

$\frac{9.525}{4}$ = $2.38 (American money)

QUESTIONS:

1 - How many meters are there in 6.5 yards?

2 - Convert 10 inches into centimeters.

3 - Convert 3.5 meters to inches.

4 - Convert 1 kilometer to feet.

5 - How many kilograms are there in 1.5 pounds?

UNIT IX - READING THE SCALES

Lesson No. I — The Rule and The Yardstick

You can read the scale on an ordinary twelve-inch rule. You should be able to find halves and quarters. Perhaps you can even read eighths and sixteenths. You should also be able to read the scale on a yardstick - that is, if you understand the scale on the rule.

Suppose we look at just an inch section on the rule. We will pretend that this is an inch. (It is actually much longer, so that it will be easier to see the divisions.)

Halfway between the left end of the rule and the 1 we see a large line. This stands for 1/2 inch.

If you will look at your rule again, you will see that these halves are halved, by smaller lines. These halves of halves are <u>quarters</u>.

The arrow above indicates 1/4 inch.

The <u>quarters</u> are halved, making eighths.

Notice that 1/8 is one-half of a quarter.

Now, if you halve the eighths you will have sixteenths.

15021 120.2

Machinists and some other craftsmen carry steel rules they call scales where the sixteenths are halved into thirty-seconds, and these thirty-seconds are halved again to make sixty-fourths of an inch. For making measurements accurate to smaller parts than sixty-fourths, they usually use a precision instrument called a micrometer, with which they can measure in thousandths of an inch.

ASSIGNMENT:

Using a pencil with a hard lead and a fine point, indicate the following points:

a. 15/16 inch

b. 3/16 inch

c. 1/8 inch

d. 3/4 inch

e. 5/8 inch

f. 3/8 inch

g. 9/16 inch

150 2

UNIT IX - READING THE SCALES

Lesson No. 2 — The Inch vs. the Centimeter

Compare a meterstick with a yardstick. Of course you will find that the meterstick is more than three inches longer than the yardstick. The important difference, however, is that it is divided into tenths, hundredths, and thousandths instead of thirds, quarters, eighths, sixteenths, etc.

Let us compare an inch with a centimeter.

THE INCH

THE CENTIMETER

In scientific fields, nearly all measurements are made in units, tenths, hundredths, hundreds, thousandths, thousands, etc. Many measurements are also made in percentages. In other words, scientists and technicians use the decimal system. It is so easy just to move a decimal point back and forth to divide or multiply.

On the centimeter scale below, the arrow indicates 0.7 centimeter, or 70% of a centimeter. You will see that the centimeter is divided into ten equal portions (millimeters). So all you have to do is to indicate the line at the seventh division.

Where would 0.4 centimeter be? 0.9 centimeter?

Can you find 0.7 inch or 70% of an inch? Or 0.2 inch? You will find this very difficult.

150°3

The word decimal comes from the Latin word decimus meaning tenth, from decem, meaning ten. Perhaps no one really knows where the Latins got the word.

Let's look at the number 1.

When it stands alone, it is understood that there is a decimal point to the right.

1 means 1.

If we put a decimal point in front of it, it becomes one-tenth or 1/10.

.1

Going back to 1, if we move the decimal point one place to the right, it will be necessary to add a zero before we can move it one place in that direction. So it becomes

10.

Now you can see why we call a scale like the following a decimal scale. From it we can read directly in units, tenths, and sometimes even hundredths.

There are ten equal portions between the 3 and the 4. If we look at arrow A, we read 3.3, since it is 3/10 of the distance between 3 and 4. Likewise, arrow B is 9/10 of the distance between 3 and 4, making that point 3.9.

15024

ASSIGNMENT:

The diagram below represents a centimeter. Draw arrows to the points requested. (Use a hard lead and a sharp point.) Label each arrow.

a.	0.7	d.	0.9
b.	0.5	e.	0.1
c.	0.2	f.	0.4

150 2 2 0 1

Fig.: IX-3-3

In Figure 3,

A points to 4.5	D points to 4.225
B points to 4.05	E points to 4.775
C points to 4.45	F points to 4.025

The following diagram represents a centimeter.

Fig.: IX-3-4

(a) indicates 0.05 centimeter or 0.5 millimeters
(b) indicates 0.1 centimeter or 1 millimeter
(c) indicates 0.2 centimeter or 2 millimeters
(d) indicates 0.5 centimeter or 5 millimeters
(e) indicates 0.65 centimeter or 6.5 millimeters
(f) indicates 0.825 centimeter or 8.25 millimeters
(g) indicates 0.975 centimeter or 9.75 millimeters

Study the above very carefully before going into the assignment.

15027

ASSIGNMENT:

1 - The diagram below represents the space from the 3- to the 4-centimeter marks on a scale. Draw arrows to the points requested.

(Use a hard lead and a sharp point.) Label each arrow.

a.	3.5 cm.	d.	3.25 cm.	g.	3.925 cm.
b.	3.75 cm.	e.	3.375 cm.	h.	3.65 cm.
c.	3.15 cm.	f.	3.225 cm.	i.	3.875 cm.

Using a hard, sharp pencil, draw arrows to the following points on the above scale. Label each arrow.

a.	1.5	f.	2.75	k.	5.7
b.	1.9	g.	5.25	l.	7.55
c.	7.2	h.	6.05	m.	2.5

UNIT X - THE SLIDE RULE

Lesson No. I — Description and History

In the first quarter of the seventeenth century - 1600 to 1625 - the English-speaking man was experiencing an unusually active era. In this short 25-year span of time in the English world, future generations were given the mathematical tools that make possible most of the calculations in electricity. It was during this time that the Mayflower Compact was made; it and the Virginia Assembly of 1619 are recognized as the foundation stones of American institutions and the model of democracy for the rest of the world. It was during this time that the great English scientist and theologian, Rev. Edmund Gunter, discovered the importance of certain trigonometric ratios, compiled them into tables, and put them into use in solving problems in navigation and astronomy. He made a two-foot rule of tables called Gunter's scale. That and Gunter's line, which followed, was the forerunner of today's slide rule.

The slide rule is a marvelous instrument that will let you make calculations very quickly - even when they involve large or complicated numbers.

During this course - this year - you will be expected to learn only a few operations on the slide rule. Next year you will learn more. Of course, some of you will wish to go farther than the instructions of this book will cover. In that case, you will have the manual which came with your slide rule.

This year you will learn to use the C scale, the D scale, and the CI scale. Please note that the CI scale is not the C-one scale, but the C-I (I as in Iowa) scale. The CI scale is often called the reciprocal scale. You will use it for finding reciprocals, which you will need to do on many occasions. You will also use it in multiplying on many occasions to eliminate extra moves of the slide.

Let's look at just one scale of the slide rule. Let us examine the D scale, for example. You will notice that there is less distance between 8 and 9 than there is between 7 and 8, and less between 7 and 8 than there is between 6 and 7. Between 1 and 2 there is so much distance that the tenths are numbered. This gives much greater accuracy when working in this area than when working with higher numbers.

15030

For instance, let's find the place for the number 1,265.

Now let's read another four-digit number, this time between 9 and 10, at the end of the scale. Let's try to point out 9,575. There is so little space here that accuracy must suffer to some degree.

ASSIGNMENT:

1 - Who was Rev. Edmund Gunter?

2 - Which scale on the slide rule is called the reciprocal scale? What is a reciprocal?

3 - On your slide rule, find the following locations:

a. 25	f. 225	k. 46
b. 35	g. 135	l. 735
c. 15	h. 575	m. 895
d. 175	i. 1355	n. 1755
e. 95	j. 62	o. 9755

15031

UNIT X - THE SLIDE RULE

Lesson No. 2 — Logarithms And The Scales

Look at your slide rule. You will see that the C and D scales are identical. The only difference is that the C scale is on the part which slides in and out of the rule (called the slide), and the D scale is on the larger part (called the rule). The D scale is directly under the C scale. These two scales are adjacent (right next to each other) because they are the most-used scales. They are the ones that we shall study now.

In the previous lesson you learned that Rev. Gunter used two pieces of apparatus called Gunter's scale and Gunter's line to find answers to mathematical problems. Let us see how he did that.

You have heard of logarithms, but you still haven't had to study them in school. You know by now that $10^2 = 100$ and that $10^3 = 1{,}000$. The little 2 or 3, placed behind and slightly higher than the 10, is called an exponent. The 10 is called the base. These exponents are sometimes called logarithms, especially when they are used to shorten long mathematical problems.

Logarithms are usually to one of two standard bases. When 10 is used as the base, the logarithms are called common logarithms. In the more complex problems in electrical engineering, natural (or Napierian) logarithms are used. Natural logarithms are to a base which has a numerical value of 2.71828. This figure is represented by the Greek letter epsilon which looks very much like our letter "e", and often, in print, when there is no type for the Greek letter, we use our letter "e". We should never call this "e" when we are speaking of it, however, because 2.71828 is epsilon.

When we see a notation like this:

$$e^{3.7687}$$

The figure 3.7687 is a natural logarithm.

When we see a notation like this:

$$10^3$$

The figure 3, besides being an exponent, is also a common logarithm.

15031
15032

The nice thing about logarithms is the fact that we can make long mathematical problems into short ones by using them. Let us look at a very simple example, just to give you an idea of what logarithms are all about.

Instead of saying 1,000 X 1,000, and going through the process of multiplying them in the old-fashioned way, we may set the problem up in this manner:

$$10^3 \times 10^3 = 1{,}000{,}000 \text{ or } 10^6$$

If you can set up your numbers as powers of the base 10 (and this can be done easily, with tables), then to multiply numbers, you simply add the exponents.

The slide rule is based on logarithms. We multiply on the slide rule by adding!

Let us see, now, why the progression of the numbers on the scales of the slide rule are not <u>linear</u>, as they are on an ordinary meterstick or yardstick, but nonlinear - that is, the spacings between no two numbers are the same.

Let's use the number 2 as a base, and use consecutive numbers for exponents.

$$2^1 = 2$$

$$2^2 = 4$$

$$2^3 = 8$$

$$2^4 = 16$$

$$2^5 = 32$$

Now, see how these numbers look on a graph.

12034
15033

Fig.: X-2-1

The word linear means "in a straight line." See how nonlinear the graph is. This run of numbers (2, 4, 8, 16, etc.) is a logarithmic or exponential progression.

Logarithms are a wonderful tool for calculating. For exact figures, we can use tables of logarithms; for approximate figures, obtained very quickly, we use the slide rule instead.

In multiplying with the slide rule, all we are doing is adding logarithms. In dividing with the slide rule, we are subtracting logarithms.

ASSIGNMENT:

1 - In the expression 10^4, which number is the base and which is the exponent?

2 - What is the difference between an exponent and a logarithm?

15034

3 - What are natural logarithms?

4 - What is the base of common logarithms?

5 - When we see "e" used as a base for logarithms, what do we call the "e"?

UNIT X - THE SLIDE RULE

Lesson No. 3 — Slide Divisions

Since there are varying distances between all the divisions on the slide rule, it is necessary for us to stop at this time and become familiar with those divisions. We shall examine that portion of the scale between the 1 and the 2, and point out the correct reading of figures which fall between these divisions.

Fig.: X-3-1

A	points to	101	E	points to	141
B	points to	105	F	points to	1595
C	points to	11	G	points to	196
D	points to	12			

Of course, you must understand that at A, the 101 could mean 1.01 or 10.1 or 1010 or 0.0101 or even 101,000,000. The slide rule gives only <u>significant figures</u>. It is necessary for the operator to place the decimal. The 196 in G can mean 0.196 or 1.96 or 19.6 or 1960 or even 196,000,000.

15036

There is less space between the 2 and the 3 than between the 1 and the 2, and the divisions are quite different. Each division stands for two-tenths of the distance between the larger lines, so special care is needed in reading numbers on this part of the scale.

Fig.: X-3-2

A	points to	21	E	points to	262
B	points to	218	F	points to	276
C	points to	232	G	points to	287
D	points to	241	H	points to	295

The scale between the 3 and the 4 is just like the scale from 2 to 3 except that the spaces are smaller. The scale between the 4 and the 5 may be similar to these, or it may be like the remaining portions of the slide rule.

The spaces between 5 and 6, 6 and 7, 7 and 8, 8 and 9, and 9 and 10 are divided into the same kinds of divisions. Let us examine one type of scale between 4 and 5.

Fig.: X-3-3

A	points to	41	E	points to	4675
B	points to	42	F	points to	4825
C	points to	435	G	points to	492
D	points to	455			

15037 12039

1 - On the above scale, point out, as before, the following values:

A - 123	F - 1605	K - 1700
B - 159	G - 1225	L - 1095
C - 110	H - 1358	M - 1202
D - 105	I - 1405	N - 1650
E - 1365	J - 1015	O - 1154

2 - On the above scale, point out:

A - 250	F - 219	K - 283	P - 249
B - 290	G - 270	L -2065	Q - 258
C - 210	H - 272	M - 247	R - 287
D - 212	I - 275	N - 291	S -2475
E - 216	J -2200	O - 223	T - 201

15038

1501

SCHOOL: PETERSBURG, VIRGINIA FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: III FUEL SYSTEM

MILESTONE: II CARBURETOR - SINGLE BEARREL (Cont.)

PERFORMANCE OBJECTIVE NO: 2 TITLE: Remove, Disassemble, Reassemble, Test and Adjust Carburetor

CONDITIONS:

LEARN	REFERENCE	SOURCE
7. "Servicing Automatic Chokes"	7. Continuous Film Loop # 8367	7. Resource Materials Center
8. Carburetion and Fuel System	8. Teaching Machine cards 2D, 3A, 3B, 3C, and 3D	8. Teaching Machine (Shop)

3 - On the above scale, point out:

A - 42	D - 447	G - 476
B -4200	E - 434	H - 429
C - 455	F - 401	I - 461

UNIT X - THE SLIDE RULE

Lesson No. 4

Multiplying

Now we will learn to multiply on the slide rule. For example, 2 X 3.

Fig.: X-4-1

Place the left index (the 1 on the C scale) over 2 on the D scale.

Fig.: X-4-2

Slide the cursor to the right until the hairline is over the 3 on the C scale. Look under the hairline on the D scale and observe the answer - 6.

Now multiply 3 X 2. Place the left index over the 3 on the D scale. Move the cursor until the hairline is over the 2 on the C scale. Observe the answer, 6, on the D scale under the hairline. Note that it doesn't matter which way you multiply - 2 X 3 or 3 X 2 - you may suit your own convenience.

150401

Fig.: X-4-3

Examine the left end of the C and D scales and the number 2. The extreme left end is 1. You will also notice another 1 near the left end, but if you examine more closely you will see that that is a one-tenth (1/10) division between the end and the 2 (or between 1 and 2). So this is not 1, but 11.

Later when you understand the placement of the decimal point, you will see that it could also be 1.1, 0.11, 0.011, 0.0011, or even 11,000 or 11,000,000.

In the figure below, the index is above the number 14 on the D scale. This could mean 14 or 1.4 or 0.14 or 0.014 or even 14,000.

Fig.: X-4-4

15041

Now let us multiply 14 X 2. Follow these steps.

STEP 1. *Opposite 14 on D, set LEFT index of C.*

STEP 2. *Opposite 2 on C, read answer (28) on D.*

Fig.: X-4-5

Had the problem been 1.4 X 2, the answer would have been 2.8. Had the problem been 14 x 20, the answer would have been 280.

ASSIGNMENT:

Multiply the following with your slide rule:

1 - 1.3 X 2; 13 X 2

2 - 2 X 1.5; 2 X 15

3 - 2 X 2.5; 2 X 25

4 - 2.5 X 1.6; 2.5 X 160; 2.5 X 16

5 - 1.5 X 3; 15 X 3; 15 X 0.3

6 - 1.25 X 20; 125 X 2

7 - 17 X 2; 1.7 X 20

8 - 1.75 X 2; 175 X 2

9 - 2.5 X 2; 26 X 2; 27 X 2; 28 X 2

10 - 2.5 X 12; 2.5 X 1.2

15042

UNIT X - THE SLIDE RULE

Lesson No. 5 Using The Right Index

With your slide rule, multiply 8 X 7. Do this before you read any farther.

If you tried to multiply 8 X 7, you found that it was impossible to move the cursor to 7 after you placed the left index over 8 on the D scale - that is, if you used the left index, as you have been doing up to this point. So now is the time to learn that the slide rule has two indexes - the right as well as the left. The right end of the slide is the right index, and it is this index that you must use to multiply 8 X 7.

Place the right index over 8 on the D scale, and move the cursor until the hairline is over 7 on the C scale. Then, under the hairline on the D scale, you will find the answer, 56.

Fig.: X-5-1

ASSIGNMENT:

With your slide rule, multiply the following:

1 - 9 X 8; 9 X 5; 9 X 11

2 - 8 X 5; 8.5 X 4; 5 X 8

3 - 5 X 9; 7 X 5; 5 X 7.2

4 - 4 X 9; 8 X 12; 8 X 12.5

5 - 8.5 X 11; 8.5 X 2; 4 X 8.5

15043 12044

UNIT X - THE SLIDE RULE

Lesson No. 6 Placing the Decimal (I)

We have been repeating, over and over, that a figure on the slide rule may have the decimal point placed anywhere. For instance, 6 on the slide rule could be 6 or it could be 0.6 or even 6,000 or more or less.

Multiply 220 X 400

Your slide rule will give you 88. You know, of course, that the answer must be much greater, and, with a little time, you can place the decimal by a careful consideration of the two given numbers. We can't always spare that time. We use the slide rule because we need to conserve time. There are two rules which are very simple; and these two rules will always tell us just where the decimal belongs.

The number 220 is the same as 220. (with a decimal point). Any time a figure stands without a decimal point, it is understood that there <u>is</u> a decimal point to the right of the figure. For example, 1 is 1. or 1.0 or 1.000 (with as many zeros as you might wish to have following the decimal point - they do not change the value of the number).

An INTEGER is anything complete or whole.
An INTEGRAL DIGIT is a whole number - one which does not have a decimal <u>before</u> it.

240.5

The 2, the 4, and the 0 in the above figure are all <u>integral digits</u>. The 5 which follows the decimal point is not an integral digit, because it is not a whole number. Following the decimal point, it must be less than 1.

Now, if you add the integral digits in the expression 220 X 400, you have 6; and if you subtract 1, leaving 5, you have the number of integral digits in the answer.

220 X 400 = 88,000

15044

It was necessary to add three zeros behind the 88 to bring the integral digits to 5 in the answer.

Multiply 124.5 X 22.5

Your slide rule reads approximately 280.

124.5 has three integral digits. 22.5 has two integral digits. The total number of integral digits in the expression, minus 1, equals 4. So, the answer must have 4 integral digits. Since you can read no more than three digits here for your answer, it is necessary for you to add a zero. The answer is 2,800. If you work it out on paper, however, the correct answer is 2801.25, but 2,800 is considered within slide-rule accuracy. In most electrical calculations, slide-rule accuracy is acceptable.

Multiply 0.0018 X 2,000

Your slide rule reads 36.

0.0018 has two zeros <u>after</u> the decimal. These two zeros are negative in their effect on the number of integral digits in the expression. The number 2,000 has 4 integral digits, and the number 0.0018 could be said to have -2 integral digits. Therefore, you subtract the 2 negatives from the 4, leaving 2. Now we must, according to the rule, subtract another 1, so that the answer will have only 1 integral digit. The answer, then, is 3.6.

Multiply 0.0018 X 20

This time the two negative zeros completely cancel the two integrals in 20. We must again subtract 1, so that will leave us with a net of -1 integral digits, and we will have to place a zero in front of our answer, .036 (or, as this is generally written, 0.036).

If you will go back and repeat the work we have done in this lesson, you will see that in each problem we moved the slide to the right and used the left index in our operation. If we had had to move the slide to the left, using the right index, we would not have used the above rule, which we will call Rule 1.

R U L E 1: When you move the slide to the right, add the number of integral digits in the multiplier to those in the multiplicand and then subtract one; the result will be the number of integral digits in the answer.

12046
15045

Read again the rule which you have just studied and examine each of the problems shown below. Make sure you understand just how the correct answers were reached.

160 X 24	=	3,840
1,500 X 30	=	45,000
240 X 25	=	6,000
0.35 X 200	=	70
0.035 X 200	=	7
0.0035 X 200	=	0.7
0.0035 X 20	=	0.07
0.0035 X 2	=	0.007

ASSIGNMENT:

Do the following problems, place the decimals, and give the answers within slide-rule accuracy.

1. 21 X 3.000
2. 190 X 421
3. 18 X 0.003
4. 180 X 3,000
5. 2.5 X 0.2
6. 250 X 0.02
7. 2,500 X 0.02
8. 2,400 X 4,000
9. 215 X 0.42
10. 235 X 3.34
11. 0.0019 X 26,500
12. 1,860 X 0.444
13. 18.6 X 44.4
14. 222 X 3,330
15. 315 X 2,920
16. 3.15 X 2,920,000,000
17. 0.00315 X 2,920,000
18. 0.0315 X 0.00292
19. 28 X 0.000186
20. 200 X 2,000

15046

UNIT X - THE SLIDE RULE

Lesson No. 7 Placing the Decimal (II)

R U L E 2: When the slide is moved to the left, add the number of integral digits in the multiplier to those in the multiplicand. The sum will be the number of integral digits in the answer.

Notice that when the slide is moved to the left, the 1 is not subtracted from the sum of the integral digits, as was done when the slide was moved to the right.

Multiply 850 X 400

There are 6 integral digits shown above.

Your slide rule shows 34 when you perform the multiplying operation, so your answer is 340,000. You must add the four zeros so that your answer will contain the six integral digits.

Multiply 0.480 X 5

Your slide rule gives you an answer of 24.

The 0.480 contains no integral digits, since the decimal point is to the left, so 0.480 does not count in placing the decimal. The number 5 has one integral digit - the only integral digit in the problem, so the answer must have just one integral digit, and will be 2.4.

Study the following problems and answers.

Apply the rules and make sure that the answers are right.

90 X 8,000	=	720,000
0.9 X 8,000	=	7,200
840 X 50	=	42,000
840 X 0.002	=	1.68
0.096 X 0.003	=	0.000288
0.088 X 0.05	=	0.0044

15047

ASSIGNMENT:

Solve the following problems, making sure that the decimals are correctly placed.

1. 48 X 950
2. 840 X 625
3. 290 X 0.9
4. 540 X 0.08
5. 630 X 5.5
6. 825 X 4.25
7. 0.92 X 0.004
8. 23 X 0.000196
9. 860 X 2,460,000
10. 0.546 X 3,400
11. 775 X 885
12. 262 X 0.194
13. 843 X 72
14. 94.2 X 0.7
15. 7.2 X 0.4
16. 0.6 X 0.005
17. 65 X 58
18. 24 X 3600
19. 36.5 X 55.4
20. 0.173 X 0.0162

UNIT X - THE SLIDE RULE

Lesson No. 8 — Dividing (I)

You will quickly see that dividing on the slide rule, just as in arithmetic, is very much the opposite of multiplying. Suppose you have a problem like this:

$$6 \div 3 \quad \text{or} \quad 6/3$$

State it as <u>6 divided by 3</u> instead of saying <u>3 into 6</u>, as is often done. This will lend itself very conveniently to doing division problems as the reverse of multiplying with the slide rule. If you have 6 divided by 3, take the first number first.

1. Place hairline over 6 on the D scale.
2. Slide 3 on the C scale under hairline.
3. Read answer on the D scale under the index.

Fig.: X-8-1

The answer is always read on the D scale, the same as with multiplication. The answer here, of course, is 2.

Division problems can also be worked in another way, but we will follow this way.

EXAMPLE 2: $277 \div 25$ or $277/25$

Place hairline over 277 on the D scale, move the slide so that 25 on the C scale will also be under the hairline. The significant part of the number of the answer will be seen under the index - 111.

15049 12020

Fig.: X-8-2

Certainly you know that the answer is not 111. There couldn't be 111 24's in 277 - so it must be 11.1. This is done through "common sense" placement of the decimal. If the answer is such that it is not this easy, you can use the following rule.

RULE: IN DIVISION, WHEN YOU MOVE THE SLIDE TO THE RIGHT, SUBTRACT THE NUMBER OF INTEGRAL DIGITS IN THE DIVISOR FROM THE NUMBER OF INTEGRAL DIGITS IN THE DIVIDEND AND THEN ADD 1. THIS WILL GIVE YOU THE NUMBER OF INTEGRAL DIGITS IN THE ANSWER.

In Example 2, the dividend (277) has three integral digits and the divisor (25) has two integral digits. Following the rule, we subtract 2 from 3 and add 1. This gives us 2. There are two integral digits in the answer - 11.1.

ASSIGNMENT:

Find the answers to the following:

1. $9 \div 3$
2. $90 \div 30$
3. $25 \div 12.5$
4. $50 \div 25$
5. $\frac{600}{2.5}$
6. $\frac{45}{19}$
7. $\frac{555}{185}$
8. $\frac{9.45}{2.1}$
9. $\frac{83.5}{35}$
10. $\frac{5,100}{204}$

15050

UNIT X - THE SLIDE RULE

Lesson No. 9 — Dividing (II)

If we have to divide 1955 by 387

$$1955 \div 387 \quad \text{or} \quad \frac{1955}{387}$$

we do just as we did in the last lesson. We place the hairline over the dividend (1955) on the D scale and then move the slide until the divisor (387) on the C scale is under the hairline also. Under the index you will read the significant numbers of the answer - 505. Is the answer 505, or is it 50.5, 5.05, or even 0.505?

For this example we have another rule, because we moved the slide to the <u>left</u> instead of to the <u>right</u>.

RULE: IN DIVISION, WHEN YOU MOVE THE SLIDE TO THE LEFT, SUBTRACT THE NUMBER OF INTEGRAL DIGITS IN THE DIVISOR FROM THE NUMBER OF INTEGRAL DIGITS IN THE DIVIDEND AND THIS WILL GIVE YOU THE NUMBER OF INTEGRAL DIGITS IN THE ANSWER.

What difference did you notice between this rule and the one given in the last lesson, for cases where you move the slide to the right? It is the same except here, when you move the slide to the <u>left</u>, you <u>don't add 1</u>.

So in the example above, the divisor (387) has 3 digits. The dividend (1955) has 4 digits. 3 from 4 = 1, so the answer must be 5.05.

EXAMPLE 2:

$$195.5 \div 3.87 \quad \text{or} \quad \frac{195.5}{3.87}$$

Place hairline over 195.5 on D scale. Move slide until 3.87 is also under hairline. Note that the index rests over 505 on the D scale.

1 (the number of integral digits in the divisor) from 3 (the number of integral digits in the dividend) equals 2. There are two integral digits in the answer; so the answer must be 50.5.

15051

ASSIGNMENT:

1. $8 \div 6$

2. $9 \div 3$

3. $6 \div 2$

4. $95 \div 4.75$

5. $8500 \div 42.5$

6. $45 \div 9$

7. $465 \div 517$

8. $1545 \div 38.7$

9. $17650 \div 50.5$

10. $\frac{405}{5.06}$

11. $\frac{3675}{3.70}$

12. $\frac{20.6}{9.5}$

13. $\frac{455}{7.04}$

14. $\frac{5.65}{0.9}$

15. $\frac{8.15}{0.7}$

16. $\frac{7.7}{8.2}$

17. $\frac{8350}{9550}$

18. $\frac{23}{35}$

GEORG SIMON OHM (1787–1854).

German physicist and discoverer of the famous law in electricity bearing his name. In 1826, while teaching mathematics at a gymnasium in Cologne, he published his famous paper on the experimental proof of his law. At the time of his death he was professor of experimental physics in the university at Munich.

15034

UNIT XI - OHM'S LAW

Lesson No. 1 George S. Ohm

In the summer of 1787, big things were doing in Philadelphia. A few young fellows were standing on the corner of Market and Fourth watching the girls go by. There were certainly fewer young men in the Camden-Philadelphia area then than now, but we can be assured that they were discussing the same topics being discussed on the same corner today. One of the bolder ones gave a low whistle when a young girl with ribbons in her hair came walking by. She was carrying a basket containing several pounds of butter covered neatly by a freshly laundered doily. She was hurrying home for supper. Her mother had taken in several guests who were in Philadelphia to attend the Philadelphia Convention. It was at this convention, you remember, that our Constitution had the breath of life and reality put into it.

Yes Philadelphia was alive. The nation was new. Great men were building the foundations of our society. The cool breezes off the Delaware gave a sparkling feeling to one's blood. The girls were beautiful, and the boys knew it.

Over in Germany, a loud, bellowing baby was born that same year. His lungs were good, and his father's ringing ears could testify to that. Mr. and Mrs. Ohm, his parents, named him George; and it is said that, upon being told about the Philadelphia Convention, Mr. Ohm said that it was good that the Atlantic Ocean separated Germany from America, for otherwise the delegates would not be able to hear one another because of little George's bellowing.

15023

15054

Little George Simon Ohm grew up, learning to love sauerkraut, pig knuckles, and knockwurst. He also became a professor of mathematics, and was heard across the Atlantic Ocean - across the Pacific, and all the other oceans of the world. There is no country where Ohm's Law is not known.

This is Ohm's Law:

$$I = \frac{E}{R}$$

I equals E over R. Remembering this simple rule (or equation) gives you the key which opens the door to the knowledge of electricity.

This was not known until George Ohm discovered that "the current in a circuit is equal to the applied voltage divided by the total resistance in the circuit." We could expand the above formula to read: current (in amperes) = $\frac{\text{EMF (in volts)}}{\text{Resistance (in Ohms)}}$

The sumbol Ω (the Greek letter omega) is used for ohms.

It is like this:

Some people use this magic triangle:

15055

T2020

By covering that which is wanted, the formula for finding it is shown. Suppose you want to find E (the voltage). Place your finger over E, and the triangle shows that E equals I·R.

If you wish to find R, place your finger over R, and the triangle tells you that R equals E over I - or the voltage divided by the current.

It will be entertaining and beneficial to you if you will substitute other values for voltage and resistance for the battery and lamps shown above and solve the problem for I, for E, and for R.

15056

UNIT XI - OHM'S LAW

Lesson No. 2 — Resistors in Series

When resistors are connected like this they are connected in series. The above is a pictorial diagram--or a picture of the connection. Below is the schematic diagram of the same series resistors.

To find the total resistance of a circuit when the resistors above are connected in series, one may simply add the individual resistances like this:

R_t (total resistance) = $R_1 + R_2 + R_3$

$R_t = 4 + 5 + 2 = 11$

It does not matter how many resistors you add to the series circuit, each resistor adds to the total resistance; and the more resistive the circuit becomes, the less the current will be, as long as the applied voltage remains the same.

If you increase the voltage applied to a series circuit, the current will increase; and that increase will be in direct proportion to the increase in the applied voltage. That is, as the voltage increases, the current will increase.

Problem: How much current will flow in a series circuit consisting of three resistors of 1, 3, and 1 ohms, if the applied voltage is 10 volts?

$R_t = R_1 + R_2 + R_3 = 1 + 3 + 1 = 5$ Ohms

$$I_t \text{ (total current)} = \frac{E_a \text{ (applied voltage)}}{R_t}$$

$$I_t = \frac{10}{5} = 2 \text{ Amperes}$$

15057

PROBLEMS

1.

Find: R_t, I_t

2.

Find: R_t, I_t

3.

Find: R_t, I_t

4.

I_t = 1 Ampere, R_t = 90 Ohms. Find $E_{applied}$.

5.

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: III. FUEL SYSTEM

MILESTONE: II. CARBURETOR-SINGLE BARREL

PERFORMANCE OBJECTIVE NO.: 2 TITLE: Remove, Disassemble, Reassemble, Replace, and Test Carburetor

CONDITIONS:

Assignment is to be performed on complete automobile

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective cover on front seat of automobile
2. Move vehicle into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper manual and turn to appropiate chapter
6. Select proper tools and materials
7. Disconnect crankcase vent line from air breather
8. Remove air breather assembly
9. Disconnect fuel line
10. Disconnect vacuum line
11. Disconnect throttle linkage
12. Disconnect automatic choke tube
13. Remove nuts attaching carburetor to manifold
14. Remove carburetor from manifold
15. Disassemble carburetor following steps as outlined in the manual

PERFORMANCE CRITERIA:

6. 
E_a = 150 volts, I_t = 25 Amperes
Find R_t

7. 
R_1 = 20 Ohms, R_2 = 10 Ohms, R_3 = 15 Ohms,
R_4 = 5 Ohms.
Find E_{R_1}, I_{R_4}, I_{R_2}.

8. 
E_{R_1} = 50 Volts, R_1 = 25 Ohms, E_{R_2} = 30 Volts
Find R_t and $E_{applied}$.

15059

UNIT XI - OHM'S LAW

Lesson No. 3 — Resistors in Series Experiment

OBJECTIVE: To better understand resistors in series and to compare actual measurements with mathematical calculations.

MATERIALS:
- 1 2.2K resistor
- 2 1K resistors
- 1 D-C power supply, variable, 0-50 V. or higher
- 1 Vacuum tube voltmeter
- 1 Volt-ohm meter

Connect as follows, and measure E_{R_1} (using vacuum tube voltmeter "VTVM"). Calculate I_t.

Connect the VOM (volt-ohm meter) in series with the circuit. Measure the current and compare that value with the calculated value of I_t.

Measure the voltage drop across the VOM and calculate the resistance of the meter. Add the meter resistance to the 2.2K ohms and calculate the total current again.

Connect the circuit as follows. Measure R_t with one lead disconnected from power supply.

15060

Connect the power supply and re-check for 25 volts. Place VOM in series with the circuit and measure the circuit current, I_t. With the VOM still in the circuit, measure (with VTVM) the voltage drops across each of the resistors and across the VOM. Calculate I_t and compare it with the value indicated on the VOM.

Connect as shown below:

With power disconnected from circuit, measure total resistance. With VTVM, measure voltage drop across each resistor.

Calculate I_t.

Measure I_t with VOM in series with the circuit. Compare the value of the current as measured with the VOM with that value derived through calculation. Is there any difference? Why is there (or is there not) a difference?

QUESTIONS:

If three resistors, each valued at 1,000 ohms, are connected in series, what is the total value of resistance?

What would be the value of total resistance if another resistor valued at 1,500 ohms were connected in series with the three resistors mentioned above?

If a 90-volt battery is connected in series with the above circuit, how much current would flow through the resistors?

Why is a VOM wired in parallel and never in series?

15061

UNIT XI - OHM'S LAW

Lesson No. 4 — Resistors in Parallel

The resistors shown below are in parallel.

The following also are in parallel.

In the circuit shown below, R_2 and R_3 are in parallel, and the combined R_2 and R_3 are in series with R_1.

Let us calculate the total resistance in the circuit shown below.

The easiest way to find the total resistance when only two resistors are in parallel is to use the method known as the <u>product-over-the-sum</u> method.

15062

$$\frac{R_1 \times R_2}{R_1 + R_2} = \frac{3 \times 6}{3 + 6} = \frac{18}{9} = 2 \text{ ohms}$$

Note that R_t is less than the resistance of either single resistor.

How can the total resistance be less than one resistance? Let us imagine that each resistance is a one-foot piece of copper wire. From what you know of wire you would say that the 6-ohm resistance is half the diameter of the 3-ohm resistance. Now if we were to roll both wires and make them into one, wouldn't you expect a wire of greater diameter than the 3-ohm resistance? Therefore, you would expect that two resistances in parallel would form a resistor with less resistance than either single resistance. This is what happened.

Electrically, of course, it is merely a case of having the same e.m.f. across both resistances, and we know that they must obey Ohm's Law to give a combined resistance that is effectively less than either resistor.

If there are three or more resistors in parallel, another method can be used to calculate the total resistance - the <u>reciprocal</u> method. This uses the equation:

$$R_t = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \ldots}$$

For example, if $R_1 = 2$ ohms, $R_2 = 3$ ohms, and $R_3 = 4$ ohms, find the total resistance of the circuit if all three resistors are connected in parallel.

$$R_t = \frac{1}{\frac{1}{2} + \frac{1}{3} + \frac{1}{4}}$$

The LCD (lowest common denominator) of 2, 3, and 4 is 12. Then

$$R_t = \frac{1}{\frac{6 + 4 + 3}{12}} = \frac{1}{\frac{13}{12}}$$

$$= 1 \times \frac{12}{13} = \frac{12}{13} \text{ ohms}$$

15063

ASSIGNMENT:

In the four following circuits, solve for R_T, I_T, and the current through each resistor.

1.

2.

3.

15064

4.

15065

UNIT XI - OHM'S LAW

Lesson No. 5

More on Parallel Resistors

The problems you have seen so far have resistors of values that lend themselves readily for finding the LCD (lowest common denominator). Sometimes, if the LCD seems to go into very high values, you might wish to use the following method, which is still the reciprocal method, but uses decimal fractions where we previously used the LCD.

For example:

$$R_t = \frac{1}{\frac{1}{6.1} + \frac{1}{3.4} + \frac{1}{7.2}}$$

Instead of finding the LCD, find the reciprocals of 6.1, 3.4, and 7.2. That is, divide 1 by 6.1 for the reciprocal of 6.1; divide 1 by 3.4 for the reciprocal of 3.4, etc.

```
                    .163
6.1 ) 1.00   =   61 ) 10.000   =   0.163 57/61   =   0.164
                      6 1
                      3 90
                      3 66
                        240
                        183
                         51
```

After finding the reciprocals of the other two values we have:

$$R_t = \frac{1}{0.164 + 0.294 + 0.139} = \frac{1}{0.597}$$

```
                                  1.67
= 0.597 )1.000   =   597 ) 1000.00   =   1.67 ohms
                            597
                            403 0
                            358 2
                             44 80
                             41 79
                              3 01
```

15066

15066

This could have been done by a double use of the product-over-the-sum method.

In this method R_1 and R_2 can be reduced to the effect of a single resistor.

(A) $\frac{6.1 \times 3.4}{6.1 + 3.4} = \frac{20.74}{9.5} = 2.2$ ohms

(B) This reduces the problem to one like this:

(C) $\frac{2.2 \times 7.2}{2.2 + 7.2} = \frac{15.8}{9.4} = 1.7$ ohms

R_t = 1.7 ohms, approximately the same value as found by the reciprocal method.

After becoming better acquainted with your slide rule, you will find the method shown above to be the most convenient way of finding the total resistance of three or four resistors that are in parallel.

ASSIGNMENT:

Follow steps A, B, and C (as explained above) and find R_t in the following:

1. 
15067

2. Change R_1 to 18 ohms, R_2 to 20 ohms, R_3 to 22 ohms and solve for total resistance.

3. Change R_1 to 8 ohms, R_2 to 16 ohms, R_3 to 30 ohms and solve for total resistance.

4. Change R_1 to 14 ohms, R_2 to 16 ohms, R_3 to 32 ohms and solve for total resistance.

5. Change R_1 to 23 ohms, R_2 to 17 ohms, R_3 to 36 ohms and solve for total resistance.

Lesson No. 6 — Series-Parallel Resistors

The circuit shown below is a series-parallel circuit.

The equivalent resistance resulting from paralleling R_2 and R_3 equals 6 ohms. The product-over-the-sum method, as shown below, is the easiest way to calculate this.

$$R_{2,3} = \frac{R_2 \times R_3}{R_2 + R_3} = \frac{10 \times 15}{10 + 15} = \frac{150}{25} = 6$$

We may now reduce the circuit to show only two resistors in series.

In the above diagram, $R_{2,3}$ represents the equivalent resistance that we computed for those two resistors in parallel.

Since we now have only two resistors to work with, and since they are in series, we may add them and show them in a schematic like the following:

15070

15069

REMEMBER THIS: The voltage drop across R_2 is the same voltage drop that appears across R_3. It is not just equal to the voltage drop across R_3; it is the same, the identical drop. This is important to understand at this point, because we shall be thinking like Mr. Kirchhoff in finding the various values in the circuit. We'll be using his law, which states that in a closed loop the sum of all the voltage drops will equal the applied voltage.

Looking at the diagram, we see that the resistance of R_2 and R_3 combined is 6 ohms. R_1 is 18 ohms, and R_t is 24 ohms.

So

$$I_t = \frac{E_{applied}}{R_t} = \frac{96}{24} = 4 \text{ amperes}$$

Now

$$E = I \times R$$

$$E_{R_{2,3}} = I \times R_{2,3} = 4 \times 6 = 24 \text{ V}$$

$$E_{R_1} = I_{R_1} \times R_1 = 4 \times 18 = 72 \text{ V}$$

We know that these values are correct, because 72 V + 24 V = 96V, the total voltage drop in the circuit.

While there is only one voltage drop across a combination of parallel resistors, the current through each of these parallel resistors will be of different values unless each of them has the same value of resistance.

In this case, $I_{R_2} = \frac{E_{R_2}}{R_2} = \frac{24}{10} = 2.4$ amperes,

and $I_{R_3} = \frac{E_{R_3}}{R_3} = \frac{24}{15} = 1.6$ amperes.

15070

It can readily be seen that, if the current divides when it gets to these parallel resistors, part will go through one and the remainder of the current will go through the other. The total of these two currents must equal the total line current. If they do, this proves that the calculations were correct.

PROBLEMS:

In the circuits shown below, find R_t and I_t.

1.

2.

3.

15071

UNIT XI - OHM'S LAW

Lesson No. 7 — Analysis of A Complex Circuit

If you have a circuit like Fig. 1 shown below, and wish to do a complete circuit analysis - that is, to obtain the values of all the voltage drops and currents in the circuit - it is necessary to do some simplifying.

Notice that the circuit is composed of three distinct portions: a group of resistors in parallel, from A to B; a single resistors R_5, from B to C; and a pair of resistors in parallel, from C to D.

Fig.: X1-7-1

It is first obvious that R_2 and R_3 are in series. We can add the values of these two resistors for the sake of simplicity. We obtain a value of 40 ohms for $R_{2,3}$, which is in parallel with R_1 and R_4. This is shown in Fig. 2:

Fig.: X1-7-2

15072

15071

R_1, R_4, and $R_{2,3}$ may now be reduced to one resistance value by using the reciprocal method.

$$R_{1,2,3,4} = \frac{1}{\frac{1}{R_1} + \frac{1}{R_{2,3}} + \frac{1}{R_4}} = \frac{1}{\frac{1}{20} + \frac{1}{40} + \frac{1}{10}} = \frac{1}{\frac{2}{40} + \frac{1}{40} + \frac{4}{40}}$$

$$= \frac{1}{\frac{7}{40}} = 1 \times \frac{40}{7} = \frac{40}{7} = 7\overline{)40.0} = 5.7 \text{ ohms.}$$

Using the same method, R_6 and R_7 can be reduced to one value of 3.6 ohms. Actually, the product-over-the-sum method would be better than the reciprocal method since there are only two resistors involved.

We can now reduce the original circuit to an equivalent series circuit, as shown in Fig. 3.

Fig.: X1-7-3

We may now further reduce Fig. 3 to Fig. 4.

Fig.: X1-7-4

This shows the total resistance of the circuit to be 16 ohms. Next, we shall find the total circuit current.

$$I_t = \frac{E_t}{R_t} = \frac{128}{16} = 8 \text{ A}$$

15073

217 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

In Fig. 3, we reduced the voltage drops to three major divisions. Let us look at this circuit again and obtain the values of the voltage drops.

Fig.: XI-7-5

$$E_{R_{1,2,3,4}} = I \times R = 8 \times 5.7 = 45.6 \text{ V}$$

$$E_{R_5} = I \times R = 8 \times 6.7 = 53.6 \text{ V}$$

$$E_{R_{6,7}} = I \times R = 8 \times 3.6 = 28.8 \text{ V}$$

TOTAL 128.0 V.

The addition of the total voltage drops results in a total equal to the applied voltage. This proves that the figures for E are correct. This is Kirchhoff's law.

Going back to Fig. 1, we find that there are three paths for current-flow from Point A to Point B. We have now found that the voltage drop across this combination is 45.6 V, and we know the value of the total resistance in this parallel combination.

To find the value of I_{R_1}, we use:

$$I_{R_1} = \frac{E_{R_1}}{R_1} = \frac{45.6}{20} = 2.28 \text{ A}$$

Similarly, $I_{R_4} = \frac{E_{R_4}}{R_4} = \frac{45.6}{10} = 4.56 \text{ A}$

Since R_2 and R_3 are in series, 45.6 volts is not the voltage drop across either <u>one</u> resistor, but across both. So, for better understanding, we'll say

$$I_{R_{2,3}} = \frac{E_{R_{2,3}}}{R_{2,3}} = \frac{45.6}{40} = 1.14 \text{ A}$$

15073
217
15074 | 15075

We know that these three currents should now add up to the value of I_t. This is one way to check the accuracy of our calculations.

$$I_{R_1} = 2.28 \text{ A}$$

$$I_{R_{2,3}} = 1.14 \text{ A}$$

$$I_{R_4} = \underline{4.56 \text{ A}}$$

$$\text{TOTAL} \quad 7.98 \text{ A}$$

This is close enough to 8 amperes for us to accept.

This still leaves us without knowing the value of the voltage drops across the individual resistors R_2 and R_3. We know now that a current of 1.14 A flows through each of these resistors, so finding the voltage drops is simple, using Ohm's Law $E = I \times R$.

$$E_{R_2} = I_{R_2} \times R_2 = 1.14 \times 30 = 34.20 \text{ V}$$

$$E_{R_3} = I_{R_3} \times R_3 = 1.14 \times 10 = 11.4 \text{ V}$$

checking, $E_{R_2} + E_{R_3} = 45.6 \text{ V}$

Let us review how we can solve a complicated problem such as this.

(1) Examine the circuit carefully and decide what distinct portions it consists of.

(2) Reduce the resistances in each portion to a single, equivalent value.

(3) Redraw the circuit in the simplest form possible.

(4) Calculate the value of the total resistance.

(5) Calculate the value of the total circuit current.

(6) Calculate the voltage drops over each portion of the circuit.

15076

15076

(7) Going back to the original problem, calculate the current through each resistance, based on the figures for E and I that you have found.

Check your figures as you work them out.

PROBLEMS:

1. In the circuit shown, find R_t, I_t, E_{R_2}, I_{R_3}, and E_{R_4}.

2. In the circuit shown below find I_{R_2}, I_{R_3}, E_{R_2}, E_{R_3}.

15078

3. In the following circuit find the values of E_{R_3}, I_{R_3}, E_{R_2}, I_{R_2}, E_{R_5}.

4. Find I_{R_1}, I_{R_2}, I_{R_3}, I_{R_4}, I_{R_5}, E_{R_1}, E_{R_2}, E_{R_5}, and E_{R_6}.

UNIT XII - READING THE METERS

Lesson No. 1 Reading Voltages

There are numerous multimeters, or VOM's, available in this country. They vary in size, shape, sensitivity, the arrangement of the scales on the meter face, and in the number of functions possible. Once you learn how to read one, however, you will find it easy to read any of them, after a little study of their ranges, functions, and scales.

A single multimeter may be used to measure voltage, resistance, or current - and each of these over a wide range of values. In order to properly read off the particular value we are trying to measure, we must first connect our leads properly and then turn the switches on the meter to the proper positions. The needle will move to a certain position, and we must read this point on the proper scale. Sometimes we will have to mentally move the decimal point as well - but after a while this will become easy.

The FUNCTION SWITCH is the switch which changes the multimeter from an a-c meter to a d-c meter. (See Figure XII-1-1.) Some meters also have a position labeled output. This gives the same circuit conditions as the a-c position, but is there for making special a-c output measurements under special test arrangements. When the switch is on a-c it is set for all a-c measurements. However, many VOM's do not measure alternating current. In those meters, the a-c position measures a-c volts only.

When the function-switch is turned to d-c, the meter may be used as a d-c voltmeter, a d-c ammeter, or an ohmmeter, depending on where the range-switch is set.

The RANGE SWITCH (See Figure XII-1-1) is a rotary switch which lets us select different ranges for measuring voltage, amperage, and resistance with accuracy. Imagine how little accuracy there would be in measuring 3 volts on a 500-volt range. Also, imagine how much more accurately you can read 30 ohms on a range that goes up to 1000 ohms than on a range that goes to 100 K-ohms. Some meters have a range in megohms.

The different positions of the range-switch tell us the maximum amount that the meter will measure with the switch in that position. For example, if the switch points to 50V, that means it can measure from zero up to 50 volts. If the range-switch points to 10 MA, that means that the meter will measure from zero to 10 milliamperes.

15082

Let's connect our test leads (the red one to the positive jack, the black one to the common jack) and make a d-c voltage measurement. We know that we are measuring a d-c voltage, but we don't know how much. So we start at the highest range and, if the needle shows practically no movement, we drop down to the next lower range, and then on down until the needle gives us a good reading - not too near either end of the scale.

Suppose the function-switch, the range-switch, and the needle-indicator look like Fig. XII-1-1.

What are we measuring? Well, we know it is a d-c voltage because the function-switch is on DC. Since the range-switch is on 5V, we know it is less than 5 volts - 5 volts being the maximum voltage on that range.

Where is the 5-volt range? You won't see a 5-volt range, but, looking on the center scale, you will see a 50-volt range. Find it. If the range-switch is on 5V, then the 50 is read 5.0 V.

Fig.: XII-1-1

15084

You will see now that the needle is exactly halfway between 30 and 40 (or 3.0 and 4.0 on this range). Therefore the voltage we are reading is 3.5 volts d-c.

Had the needle rested here when the range-switch was on 50V, the voltage would have been read directly as 35 volts. Had the range-switch been on 500V, the voltage would have been 10 x 35, or 350 volts. Had the needle rested at the same position, while the red lead was connected to the 5KV jack instead of the positive jack, the voltage would have been 3,500 volts.

All of this sounds very difficult, but it is simply a matter of moving a decimal point. If a scale goes up to 100 and we are operating in a range going up to 1, we simply divide our reading by 100 - that is, move the decimal point two places to the left. This makes the maximum reading correct at 1.00. If the needle pointed to 40, the reading would become 0.40 (volts or amps as the case might be).

Similarly, if we are using a scale that goes up to 50V and we are operating in a range that goes up to 500V, we move our decimal point one place to the right. The maximum becomes 500V and our reading of 35V becomes 350V.

Look at the scale opposite the large arrow on Figure XII-1-2. D-c voltage values are read above the curved line, and a-c values are read below the line.

You will note that the values of a-c voltage do not correspond exactly to the d-c values. This is due to the fact that a-c must be brought in through a rectifier and that reactance is involved. You will understand this after you have learned more about electricity.

FIG. XII-1-2

15085

Look again at the range opposite the arrow. Note that, at 50 volts, the a-c reading is the same as the d-c reading, but at 10 volts, the a-c reading is lower on the scale than the d-c reading.

As a-c voltages become lower and lower, they are farther and farther from the corresponding d-c voltage readings.

Look at Fig. XII-1-3. You will see that we are reading a-c, since the function-switch is on AC. The range-switch indicates 1 volt. In this case, we do not use the 50-volt (center) scale. For readings of less than 1-volt a-c, we use the 1-volt scale. Find it. The needle rests on 2 on this scale. But since the full-scale reading is only 1 volt (and not the 10 marked on it), this reading must be 0.2 volts. Now look at the 1-volt d-c scale. (The 1-volt d-c scale is the one indicating 100 at full-scale reading. The 100 is read as 1.00 volt when the range-switch is on 1V.) We see that the needle is indicating 12 volts on the d-c range or 0.12 volts on the scale we are using. Here you can see the need for a separate scale for low a-c voltages.

Fig. XII-1-3

15087

ASSIGNMENT:

1. What is the function of the function-switch?

2. What is the purpose of the range-switch?

3. Why isn't the needle deflected as far for 0.2 volts a-c as it is for 0.2 volts d-c?

4. Using the first line below as an example, supply the missing numbers for the other lines.

Your range-switch points to:	Your meter scale goes up to:	The needle points to:	This is read as:
10	100	30	
5	50	24	
500	50	24	
100	100	72	
1	100	72	
1	10	6	
10	100	62	
50	50	43	
1	10	8	
5K	50	22	

5. Use a hard-lead pencil and, very lightly, mark the leads, switches, and the four meter faces indicating (a) 40 volts d-c, (b) 2.5 volts d-c, (c) 75 volts a-c, (d) 0.7 volts a-c on the four meter-face diagrams on the next page.

UNIT XII - READING THE METERS

Lesson No. 2 — Reading Resistance

Some meters have more resistance ranges than others. The one we are using in this lesson has only three ranges, as you will see if you look toward the right of the range-switch. With the switch on the R x 1 range, the resistance is read directly on the scale; with the switch on the R x 10 range, we multiply the scale-reading by 10. The LOW OHMS range is read on its separate scale, just below the other scale.

Look at Figure 1. If the meter is set up and reads like this, we are reading 50 ohms. (Note the position of the switches.) Should the needle be in the same position but with the range-switch on R x 10, then we would be reading 50 x 10 or 500 ohms.

The LOW OHMS range actually gives us another type of ohmmeter, and you will notice that 0 ohms is on the opposite end of the scale. This is because, when the range-switch is on LOW OHMS, we switch in a shunt-type ohmmeter instead of the series-type we have when we are switched to either the R x 1 or the R x 10 range.

Fig.: XII-2-1

15091

When you learn about shunt ohmmeters, you will learn that current is drawn continuously through them. Therefore, when this meter is switched to LOW OHMS, if left in this position the battery in the meter will soon be exhausted. Use the low-ohms range only for measuring low values of resistance.

There is a slightly greater degree of accuracy in measuring small-resistance values on the low-ohm range. Compare the distance between 0 and 20 on each scale and you will see that there is more distance (giving greater reading accuracy) on the low-ohms scale than on the regular ohms scale.

ASSIGNMENT:

On the following four figures, indicate (very lightly, with a hard-lead pencil) the following values. Show the leads coming from the proper lead jacks, the position of the switches, and the position of the needle.

1. 20KΩ
2. 750Ω
3. 5KΩ
4. 120Ω (on the low-ohms scale)

UNIT XII - READING THE METERS

Lesson No. 3 — Measuring Current

Let's look at the meter shown in Figure 1. The function-switch is on d-c; the range-switch is on 10 MA. You will see that the needle lies across 40 on the 100 d-c scale.

How many MA's does this represent? We must read the 100 scale as 10.0 MA when we use the 10 MA range. So the 40 means 4 milliamperes.

Fig.: XII-3-1

15096

If we have our meter in series with a circuit, what would we be measuring on the meter shown in Figure 3?

First, note that the function-switch is on a-c. Now since we have the meter in series with the circuit, we are reading current. (A connection across the circuit would be for measuring volts.)

The range-switch is on the 1 MA range since we are reading current, so we must be reading less than 1 MA. Look at the AC - 1 MA scale. The needle is on 14, but the scale goes to 100. Converting this to 1.00, we convert the 14 to .14. Thus we are reading 0.14 MA, a-c.

Fig.: XII-3-3

Fig.: XII-3-4

Figure XII-3-4 shows a VOM indicating a measurement of 8 MA, a-c. Make sure you see that the needle is on 8 on the AC - AMPS scale, that the function-switch is on a-c and the range-switch is on 10 MA. What would you be reading if the function-switch were on d-c and the range-switch were on 10V?

REMEMBER: Just as you do in measuring voltages, if you don't know the general range of the current you are about to measure, start with the high ranges so that you will not ruin the meter.

15100

ASSIGNMENT:

On the following four meter-face diagrams, draw the leads, switch settings, and needles to have them indicate the following values:

1. 0.6MA, d-c
2. 0.1MA, a-c
3. 2 MA, a-c
4. 2 MA, d-c

15102

UNIT XII - READING THE METERS

Lesson No. 4 — The High-Voltage Jack

The voltage range is extended in some meters by having a high-value dropping resistor in the meter, leading to a separate jack for one of the test leads. It is necessary to have physical separation of the leads to prevent arcing at the higher voltages.

To read in the 5 KV range: we connect the test lead to the 5 KV jack, set the range-switch to 5 KV, and use the 50 V scale. However we must multiply our reading by 100 (50 V x 100 = 5000 V or 1 KV).

If you connect the leads as shown in Figure 1, and the needle indicates as shown, you would be measuring 4,600 volts d-c.

Fig.: XII-4-1

Study the meter in Figure 2 and you will see that you are reading 1000 volts a-c. Note that the function-switch is on a-c, one of the test leads is in the 5 KV jack, the range-switch is on 5 KV, and the needle is on 10 on the a-c volts scale.

Fig.: XII-4-2

15105

WARNING! If there is any possibility that the voltage you are about to measure is more than 5 KV, it will be necessary to use a special high-voltage probe. The high-voltage probe has another range-extending resistor in it.

Now study the following four readings and determine what the meters are reading.

Fig.: XII-4-3

UNIT XII - READING THE METERS

Lesson No. 5 — The High-Current Jack

There is an extra-low-value shunt resistor placed in some meters so that higher values of current may be measured.

Figure 1 indicates that a d-c current of 0.9 amperes (or 900 MA d-c) is being measured. How do we reach this figure?

(1) The black lead is in the -1AMP jack.

(2) The function-switch is on d-c.

(3) The range-switch is on .1 - 1A position, giving us a 1A maximum current range, since the (-) lead is in the -1A jack.

(4) Look at the 100 d-c range. The needle is at 90. Call the 100, 1.00A. This changes our reading of 90 to 0.90A, as we mentioned above.

NOTE: It is the placement of the leads that make the range either .1A or 1A.

Fig.: XII-5-1

15110

If the leads are connected as shown on Figure XII-5-2, then we are on the .1 A range.

Fig.: XII-5-2

If the leads are connected to the meter as shown in Figure XII-5-3, it will be on the 1A range.

Fig. XII-5-3

15111

What is the meter reading in Figure XII-5-4?

Since the function-switch is on a-c and the range-switch is on a current range, we know that we are reading an a-c current. The leads come from the "POS" jack and the 1A jack, so we know that the <u>.1 - 1A</u> that the range-switch is pointing to is the 1A range instead of the .1A range. Now on the AC -AMPS scale we read 7. We know that, since the scale reads 10A maximum rather than 1 amp, we read the 10A as 1.0A and the 7 amps becomes 0.7 amps. The 0.7A, of course, may be stated as 700 milliamperes.

Fig.: XII-5-4

Study figures 5 through 8 on the next page and tell what each meter is indicating.

15113

Fig.:XII-5-5

Fig.: XII-5-8

15114

ASSIGNMENT:

On the four following meter figures indicate the following readings.

1. 700 MA DC
2. 0.7A AC
3. 300 MA AC
4. 0.3A DC

15116

15114

UNIT I

ACHIEVEMENT TEST

1. One should never use carbon tetrachloride in cleaning anything because _____

   _____

2. For what purpose is a shorting bar used? _____

   _____

3. Of what should the handle of a shorting bar be made? _____

   _____

4. What does the word lethal mean? _____

   _____

5. What type of fire extinguisher should you use on an electrical fire? _____

6. Where are the circuit breakers in the lines coming to your workbench? _____

   _____

   _____

7. How may untreated cuts and puncture wounds contribute to unsafe conditions? _____

   _____

   _____

8. Why should the preservation of students' good health be important in maintaining a safe shop? _____

   _____

   _____

15117

UNIT II

ACHIEVEMENT TEST

1. Name three reputable manufacturers of dependable soldering irons.
2. Name at least two brands of high-quality pliers.
3. Name at least two dealers in your locality who sell high-quality tools.
4. Why is buying cheap tools a false economy?
5. How can you keep your tools in proper repair?
6. For how many different kinds of jobs is the screwdriver designed?
7. What is 40/60 solder?
8. If you want a real bright, shiny appearance to your soldered connections, what kind of solder would you use?
9. What is meant by tinning a soldering iron?
10. Why is acid-core solder not used in soldering electronic equipment?

15118

UNIT III

ACHIEVEMENT TEST

1. What is the Greek word for amber?

2. How far back in history can the knowledge of electric attraction be traced?

3. What is the difference between static electricity and voltaic electricity?

4. Early scientists referred to two kinds of electricity, vitreous and resinous. What did they mean?

5. Use the word <u>electric</u> in three different sentences.

6. Use the word <u>electricity</u> in three different sentences.

7. Do all the electrons of an atom circle the nucleus in the same orbit? If not, tell how they do circle the nucleus.

8. Is the electricity produced in generators static electricity or voltaic electricity?

9. Is the electricity produced by walking over a nylon carpet voltaic or static?

10. What kind of electricity is that which causes lightning?

11. Give an example to explain the difference between an element and a compound.

12. Give an example of an alloy in common use in electrical applications.

13. Why don't the electrons fly away from the nucleus of an atom?

14. It has been said that an atom is mostly open space. Would you agree or disagree? Explain.

15. Why are the s and p electrons so important to electricians?

15119

UNIT IV

ACHIEVEMENT TEST

1. Describe the structure of an atom, either in words or with a diagram. Include: nucleus, protons, electrons, shell, atomic number.

2. What is electric current flow?

3. How fast does an electric current travel?

4. In what direction does electric current flow?

5. Name three good conductors.

6. How does a conductor differ in atomic structure from an insulator?

7. Why is copper the most commonly used conductor?

8. If an atom loses an electron, how does this affect the electrical charge of the atom?

9. Which is a better conductor, gold or copper?

10. Who made the first electric light bulb? the first radio tube?

15120

UNIT V

ACHIEVEMENT TEST

1. Name two examples where mechanical energy is employed to produce electromotive force.

2. Define the word potential.

3. The volt is the unit of measurement of what?

4. What is the difference between force and energy?

5. Is electrical pressure a universal term?

6. What is electrical pressure?

7. In what units is e.m.f. measured?

8. Where do we find chemical energy employed in producing electromotive force?

9. In what units is potential difference measured?

10. Why do we use the word difference in potential difference?

15121

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: III. FUEL SYSTEM

MILESTONE: III. CARBURETOR-TWO BARREL

PERFORMANCE OBJECTIVE NO.: 3 TITLE: Remove, Disassemble, Reassemble, Replace, and Test Two Barrel Carburetor

CONDITIONS:

BEHAVIOR:

16. Identify all parts and the functions of each
17. Reassemble carburetor following all steps as outlined in the manual
18. Make all bench adjustments as outlined in the manual
19. Clean all gasket material from base of carburetor and intake manifold
20. Install new carburetor-manifold gasket
21. Install carburetor on manifold
22. Secure carburetor to manifold with nuts
23. Reconnect fuel lines
24. Reconnect vacuum lines
25. Reconnect automatic choke tube
26. Reconnect throttle linkage
27. Start automobile and immediately check for leaks
28. Make all adjustments as outlined in the manual
29. Recheck all steps in installation and assembly
30. Install air breather assembly
31. Reconnect crankcase vent

PERFORMANCE CRITERIA:

1508

UNIT VI

ACHIEVEMENT TEST

1. What were the nationalities of: Franklin, Volta, Leclanché, and Galvani?

2. Compare the alkaline cell with the nickel-cadmium cell as to uses; as to primary-secondary type; as to advantages and disadvantages.

3. What is the voltage of four 1.5-volt cells connected in parallel?

4. Are common dry cells rechargeable? Why does <u>resting</u> sometimes seem to build up a dry cell which seemed burned out?

5. What is the electrolyte in a storage battery? What does it consist of?

6. How can you tell when a storage battery needs recharging?

7. Give two rules for getting the greatest possible service from a dry cell.

8. Give two rules for getting the greatest possible service from a lead-acid storage battery.

9. How would you connect 1.5-volt carbon-zinc cells, each capable of sustaining .25 amperes, to obtain a 6-volt supply at .75 amperes?

10. Draw a diagram showing a circuit containing a resistance and 6 dry cells - 2 paralleled groups, each consisting of 3 series-connected cells.

UNIT VII

ACHIEVEMENT TEST

1. What kind of charge will repel electrons?

2. How many mils are in ½ inch?

3. Is 10-gauge wire heavier or lighter than 20-gauge wire?

4. Do different kinds of metal conductors have different electrical resistances?

5. What is a "pot," and where do you often see them?

6. What are the resistance values of the resistors color-coded as follows:

a.	RED	RED	RED	GOLD
b.	ORANGE	YELLOW	BROWN	SILVER
c.	WHITE	YELLOW	ORANGE	
d.	WHITE	GRAY	YELLOW	GOLD
e.	VIOLET	WHITE	RED	SILVER
f.	BLUE	BLACK	BLACK	GOLD
g.	BROWN	BLACK	BLACK	
h.	GRAY	WHITE	RED	SILVER
k.	BLUE	RED	ORANGE	
m.	ORANGE	ORANGE	ORANGE	

15123

UNIT VIII

ACHIEVEMENT TEST

I. In what system are the following units used?

1. Mile
2. Inch
3. Centimeter
4. Ounce
5. Foot
6. Centigram
7. Pound
8. Liter
9. Kilogram
10. Yard
11. Ton
12. Quart

II. Change to grams:

(a) 200 centigrams
(b) 2 kilograms
(c) 550 milligrams
(d) 49 milligrams
(e) 1.9 kilograms

III. Change to millimeters:

(a) 25 centimeters
(b) 4 meters
(c) 3 centimeters
(d) 360 centimeters
(e) 97 millimeters

IV. Express the following in powers of ten:

1. 100
2. 1,000
3. 0.01
4. 0.001
5. 200,000
6. 22,000
7. 0.002
8. 1,200

V. When and where was the metric system first used?

VI. How many grams are there in (a) a kilogram (b) a milligram (c) a microgram?

15124

VII. How many ohms are there in one megohm?

VIII. Multiply and leave answer in powers of 10.

1. $3 \times 10^4 \times 2 \times 10^5$
2. $4 \times 10^{-2} \times 3 \times 10^{-3}$
3. $5 \times 10^{-4} \times 2 \times 10^6$
4. $170{,}000 \times 2{,}000{,}000$
5. $22{,}000 \times 3 \times 10^{-6}$

12124

UNIT IX

ACHIEVEMENT TEST

1. Here is a representation of an inch. By using arrows and the given letters, indicate the following points:

a. 6 1/4"	e. 6 1/8"	i. 6 9/16"
b. 6 7/8"	f. 6 5/16"	j. 6 3/16"
c. 6 1/16"	g. 7"	
d. 6 3/4"	h. 6 1/2"	

2. Here is a representation of a centimeter. By using arrows and the given letters, indicate the following points:

a. 4.7	e. 4.475	i. 4.65
b. 4.55	f. 4.3	j. 4.225
c. 4.05	g. 4.875	
d. 4.925	h. 4.025	

15125

UNIT X

ACHIEVEMENT TEST

You must make all the calculations given below through the use of the slide rule only. Do not multiply or divide by arithmetic computation.

1. 2.25 x 3.75
2. 6.7 x 1.95
3. 2,350 x 1,945
4. 8.45 ÷ 2.25
5. 950 ÷ 0.75
6. 260 x 176
7. 2,500 x 531
8. 365 x 0.87
9. 0.55 x 8,000
10. 0.955 ÷ 0.5
11. 25 x 0.7
12. $\frac{26}{11}$
13. $\frac{465}{5}$
14. $\frac{9,500}{0.75}$
15. $\frac{225}{9}$
16. $\frac{0.143}{2}$
17. $\frac{28}{10}$
18. $\frac{0.00075}{275}$
19. $\frac{9,500}{26}$
20. $\frac{21}{0.2}$

15126

UNIT XI

ACHIEVEMENT TEST

1. Find the reciprocals of (a) 5, (b) 2, (c) 4, (d) 9, (e) 23.

2. There are three resistors in parallel. R_1 = 12 ohms, R_2 = 4 ohms, and R_3 = 32 ohms. Solve for R_t.

3. Use another method for finding R_t in the problem given above.

4. In the circuit below find R_t, I_t, E_{R_1}, and E_{R_2}.

5. In the circuit below find I_{R_1}, I_{R_2}, I_{R_3}, I_{R_4}, I_{R_5}, I_{R_6}, I_{R_7}; E_{R_1}, E_{R_2}, E_{R_3}, E_{R_4}, E_{R_5}, E_{R_6}, and E_{R_7}.

15127

UNIT XII

ACHIEVEMENT TEST

On the following twelve meter figures, draw the necessary lines and pointers to make them indicate the following values. Be sure to write the value at the bottom of each one.

1. 3.5V d.c.
2. 2,000 Ω
3. 0.4V d.c.
4. 70 MA d.c.
5. 0.2 MA a.c.
6. 3,000V a.c.
7. 600 Ω
8. 10 Ω
9. 6MA a.c.
10. 0.5 MA d.c.
11. 900 MA a.c.
12. 4,600V a.c.

ABSTRACT - Developed by educators in Camden County Vocational and Technical Schools of New Jersey in cooperation with the Vocational-Technical Laboratory of Rutgers University, this is the second of a 2-part guide designed for teacher and student use in introducing the basic principles of electricity and electronics. Eight units, each consisting of three or more lessons, cover the following topics: (1) Kirchhoff's Laws, (2) Magnetism, (3) Meter Movements, (4) Multimeters, (5) Amateur Radio Licensing, (6) Alternating Current, (7) Effects of Capacitance and Inductance, and (8) Power Supplies. Other than background and explanatory information, the lessons contain assignments, questions, and illustrations. A glossary, an explanation of electrical symbols, and achievement tests are included. Part 1 of the guide is available as VT 012 902, also in this issue. (GEB)

UNIT XIII - KIRCHHOFF'S LAWS

Lesson No. 1 — Positive and Negative Numbers

If I have no money, one might say my assets are zero. If I have no money and if I owe Jim $2.00 and Bob $5.00, one might say that my assets are $7.00 below zero — or minus (-) $7.00. If, however, Charlie owes me $5.00 and Dan owes me $10.00, my assets are actually worth $8.00.

Let's look at the money owing to me as positive values and that which I owe as negative values.

Then	-2	that which I owe Jim
	-5	that which I owe Bob
	+5	that which Charlie owes me
	+10	that which Dan owes me
	+ 8	my actual worth

This is called algebraic addition. Algebraic addition involves negative as well as positive numbers. Examine the following examples:

+2	+4	-6	-3	+5	+7
-5	-3	+2	-5	+1	-8
-3	+1	-4	-8	+6	-1

How did we get these answers? "By common sense" you may say. But problems aren't always so simple, and a couple of rules will come in handy.

(1) In adding algebraically, if the signs are alike, add the numbers and use the same sign on your answer.

15138

15138

+2	-2	+7	-7
+3	-3	+1	-1
+5	-5	+9	-9
		+17	-17

(2) If the signs are unlike, subtract the smaller number from the larger and use the sign of the larger.

-2	+2	+13	-4	+4
+7	-7	- 4	+13	-13
+5	-5	+ 9	+ 9	- 9

In the examples above the numbers are arranged in a vertical position. They may also be arranged horizontally for algebraic addition, like this:

-5 -2 +3 = -4

-5 +3 -2 = -4

-2 +3 -5 = -4

In working such problems, it is usually simplest to add all the negative numbers, add all the positive numbers, and then combine the two results. In each of the above cases, this method would lead us to -7 +3, which of course equals -4.

Here are several more examples:

1. -5 +2 -1 = -4

2. -5 +2 -1 +2 = -2

3. -2 +4 +3 -1 = +4

4. +7 +2 -3 = +6

15139

In examples 3 and 4, the answers should be written simply as 4 and 6, leaving off the plus sign preceding the numbers, because a number standing alone (without any sign) is understood to be positive.

In example 4, the first digit, +7, should have been written simply as 7, since the plus sign is not needed there. If the first number is negative, as in examples 1, 2, and 3, the negative sign is needed to indicate that those numbers are not positive numbers.

Note that we can write the sum of 7 and -2 in two ways: either vertically or horizontally:

$$\begin{array}{r} 7 \\ \underline{-2} \\ 5 \end{array} \qquad \text{or} \qquad 7 \quad -2 \quad = \quad 5$$

For the second form we can also write: 7 - 2 = 5
The spacing here tells us that we are subtracting a +2 from a +7, but it works out to the same answer as adding a -2. So for convenience we often use a centered plus or minus sign.

10 - 3 - 9 + 2 = 0

PROBLEMS:

Find the algebraic sums of the following.

1. -4 - 10 + 2 - 3
2. -3 + 6 + 4 - 7 + 2
3. -6 - 3 + 2 + 9 - 4
4. 8 - 5 + 9 - 3 + 2 + 6
5. 20 + 2 - 8 + 3
6. -25 + 4 - 8 + 15
7. -4 + 35 - 5 - 10 + 40
8. 25 + 5 - 15 - 10 + 5 + 15
9. 4 - 7 + 9 - 4 - 6 - 2 - 5 - 3
10. -2 + 8 + 4 - 6 + 8 + 4 - 2 + 6

UNIT XIII - KIRCHHOFF'S LAWS

Lesson No. 2 Multiplication

You have seen how positive and negative numbers may be added algebraically. Let's see now how these positive and negative signs affect answers when the numbers are multiplied.

We know that $2 \times 4 = 8$

or $(2) \times (4) = 8$

The 2 and the 4 are positive numbers since they are without signs in front of them. If one of the numbers has a negative sign in front of it while the other is positive, the answer will be negative.

$(2) \times (-4) = -8$

or $(-2) \times (4) = -8$

If both numbers are negative, however, the answer will be positive.

$(-2) \times (-4) = 8$

RULES:

Negative x negative = Positive

(-) x (-) = (+)

Positive x positive = Positive

(+) x (+) = (+)

Negative x positive = Negative

(-) x (+) = (-)

Positive x negative = Negative

(+) x (-) = (-)

15141

In algebra, we use parentheses ( ) to show that two or more numbers are to be considered as one unit. Any operation performed on one of the numbers must be performed on the others. No doubt you have met up with this idea before.

For example, 2 times (7 - 5) might be written 2(7 - 5). If we were to perform the operation of multiplication, we would get (2 x 7) - (2 x 5) = 14 - 10 = 4. This is obviously correct, since 2 times (7 - 5) is actually 2 times 2.

Let us use the letters a, b, and c to stand for numbers - any numbers at all.

If b plus c are multiplied by a, like this: $a(b + c)$, the answer is $ab + ac$. That is, $a(b + c) = ab + ac$.

If you multiply b plus c by 4, like this

$$4(b + c)$$

the answer is $4b + 4c$. Then $4(b + c) = 4b + 4c$.

If you multiply a + b by -4, like this

$$-4(a + b)$$

the answer is $-4a - 4b$. Then $-4(a + b) = -4a - 4b$.

If you multiply a - b by -4 like this

$$-4\ (a - b)$$

the answer is $-4a + 4b$. Then $-4(a - b) = -4a + 4b$.

As you know, in electricity we work with many different letters, each standing for a particular value.

EXAMPLES:

$$4\ (R_1 + R_2) = 4R_1 + 4R_2$$

$$-10(I_1 + I_2) = -10I_1 - 10I_2$$

$$8(I_1 - I_2) = 8I_1 - 8I_2$$

$$-6(I_1 - I_2) = -6I_1 + 6I_2$$

15142

Another thing we must learn now if we are to be able to figure out circuits - which parts of an algebraic "expression" we can combine, and which we cannot.

If I told you to add 10 volts and 3 ohms, you would say - "It can't be done; they are different types of things." But if I said, "add 10 volts and 3 ohms and 2 volts and 4 ohms," you would be able to at least add the volts together and add the ohms together. The answer might not mean much, but it could be done.

$$10V + 3\Omega + 2V + 4\Omega = 10V + 2V + 3\Omega + 4\Omega = 12V + 7\Omega$$

In algebra, similarly, we cannot add different types of things, that is, different letters.

$$6a + 2b = 6a + 2b$$

But we can add (or subtract) similar types of things.

$$4a + 2a = 6a$$

$$6V - 1V = 5V$$

We might find ourselves with an expression like this:

$$2a - 4b + 3c + 6a - 2c$$

We can combine the similar parts:

$$2a + 6a - 4b + 3c - 2c$$

We get: $8a - 4b + 1c$, which is written $8a - 4b + c$. (That is, $1c$ is written as c.)

Here is something you might come across in electricity:

$$3I_1 + 4I_2 + 3I_1 - 18 = 0$$

You can combine the two I_1's but not the I_1's with the $4I_2$ or the plain number 18. They are different things. So you would write this as

$$3I_1 + 3I_1 + 4I_2 - 18 = 0$$

$$6I_1 + 4I_2 - 18 = 0$$

15143

Here is another:

$$-4I_1 - I_1 + 5I_2 - 20 = 0$$

$$-5I_1 + 5I_2 - 20 = 0$$

PROBLEMS:

Multiply:

1. $4(I_1 + I_2)$
2. $-3(b - c)$
3. $-16(I_1 + I_2)$
4. $-14(a + b - c - d + e)$

Combine:

5. $2I_1 + 3I_1 + 6I_2 + 5I_2$
6. $4a + 2b - c - 3a - 7c$
7. $10I_1 - 4I_2 + 3I_2$
8. $13x - 10y + 2z + 6y - 2z$

Multiply and combine:

9. $-2(a - b) + 12(a + b)$
10. $4(I_1 - I_2) - 2I_1 + 3I_2$
11. $-3(I_2 - I_1) - 10(I_1 - I_2)$
12. $5(I_1 - I_2) - 4I_1 + 7I_2 - 2I_2$

15144

UNIT XIII - KIRCHHOFF'S LAWS

Lesson No. 3 Law No. 1

There are two Kirchhoff laws. The first one states:

> The algebraic sum of the currents at any junction in an electrical circuit is equal to zero.

You could also state this by saying that, "The total of all the currents leaving a junction is equal to all the currents coming into it."

Suppose we have a condition like this:

Fig.: XVIII-3-1

Wire w is carrying 5 amperes of current into junction J. Wire x is carrying 7 amperes of current into junction J. Since there is only one more wire at that junction (wire y), it must be carrying away all of that current -- all 12 amperes.

Now if you want to go back and relate this situation to the first of Kirchhoff's laws, in algebraic terms, you can apply + signs to the currents coming into the junction and a - sign to the current going out and state it like this:

$$-12 + 5 + 7 = 0$$

15144
15145

Let's look at this junction and its currents:

Fig.: XIII-3-2

We must have a starting place, so let's start with conductor w and go around the junction in a counterclockwise direction, giving + values to currents going toward the junction and - values to those leaving the junction.

$$3 - 1.5 + 2 - 3.5 = 0$$

Add them. Don't the + values cancel out all of the - values? Therefore their algebraic sum does equal zero, and these current values do follow Kirchoff's law.

This is a simple law - simple in that it is so logical. It is like saying, "All that goes up must come down." All the currents going into a junction must leave that junction.

Follow the currents in the following circuit:

Fig.: XIII-3-3

15146

How much current is going into junction A? How much is leaving junction A? How much is going into junction B? How much is leaving junction B?

The algebraic equation showing Kirchhoff's first law for junction B is:

$$4 - 2.4 - 1.6 = 0$$

The equation for junction A is:

$$1.6 + 2.4 - 4 = 0$$

ASSIGNMENT:

Write the algebraic equations (demonstrating Kirchhoff's first law) for the currents at the junctions shown below.

15147

UNIT XIII - KIRCHHOFF'S LAWS

Lesson No. 4 Law No. 2

Kirchhoff's second law states that:

> The algebraic sum of the electromotive forces and the voltage drops around any closed electrical loop is zero.

This may also be stated as, "The sum of all the voltage drops in a closed electrical loop is equal to the applied e.m.f."

Look at this circuit:

Fig.: XIII-4-1

When you add the voltage drops 30 + 45 + 25 you will get 100 - the same as the applied e.m.f. (the source voltage).

The fact that the sum of their voltage drops equals the source voltage is Kirchhoff's Law No. 2.

This can be used in many ways. Perhaps you will most often use it this way:

Fig.: XIII-4-2

15148

The value of R_2 is not given. According to Kirchhoff's voltage law, the three drops must equal 90 volts. We can see voltage drops totaling 50 volts. Now we know that the other 40 volts must be dropped across R_2, since there is no other resistance in the circuit to cause this drop.

Consider this circuit:

Fig.: XIII-4-3

What is the value of the applied voltage?

We know that the sum of the voltage drops equals the applied voltage. Only two of the voltages are given. E_{R_1} is not given, but the resistance value of R_1 is given and we have the total current given. I_T flows through R_1, so:

$$E = I \times R$$

$$E_{R_1} = 2 \times 20 = 40 \text{ volts}$$

Now we have all the voltage drops. E_{R_1} = 40 volts, E_{R_2} = 80 volts, and E_{R_3} = 60 volts.

$$40 + 80 + 60 = 180$$

So the applied voltage must be 180 volts.

ASSIGNMENT:

1. Find E_{R_1}

15149

2. Find the value of the source voltage.

3. Find $E_{applied}$.

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: I. STORAGE BATTERY

PERFORMANCE OBJECTIVE NO.: 1 TITLE: Remove, Clean, Test, and Replace Storage Battery

CONDITIONS:

This assignment will be performed on a complete automobile

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective cover on front seat of automobile
2. Move automobile into proper work station
3. Raise hood on automobile
4. Place protective covers on fenders
5. Select proper manual and turn to appropiate chapter
6. Select proper tools and materials
   (Before proceeding, obtain one pound of bicarbonate of soda and a water can filled with water. Keep these items handy and use to neutralize acid or corrosion. Do not get acid on clothing or skin. If you do, immediately neutralize acid with soda water solution.)
7. Remove cables from battery
8. Submerge cable terminals in soda water solution
9. Remove battery hold-down bracket

PERFORMANCE CRITERIA:

1511

UNIT XIII - KIRCHHOFF'S LAWS

Lesson No. 5 Forming Equations

An equation is the sort of thing we have been dealing with in the past couple of lessons - an algebraic statement where one thing equals another. For example, here are some equations:

$$3 + 4 - 2 = 5$$

$$2I + 6I = 8I$$

$$E = I \times R$$

(When we speak of the two sides of an equation, we mean the parts to the left and the right of the = sign.)

An equation, as we said, is a statement. It is a short way of writing down the relationship between different things.

How would you say (in words)

$$E = IR \ ?$$

We must learn how to set up an equation for a circuit in a manner which will help us solve problems we will meet in the future. Consider the following circuit and the equation that goes with it:

Fig.: XIII-5-1

15151

We know that $E_{R_1} + E_{R_2} + E_{R_3} = E_{applied}$, or that

$$E_{R_1} + E_{R_2} + E_{R_3} - E_{applied} = 0$$

Let's review now that $E_{R_1} = I_{R_1} \times R_1$. We also know that $I_1 = I_{R_1}$ as well as the value of current through the other resistors in this series circuit.

If $E_{R_1} = I_{R_1} \times R_1$ then $E_{R_1} = 7(4)$ (that is, 7 x 4)

and $E_{R_2} = 7(6)$

and $E_{R_3} = 7(5)$

We must have polarities to these voltage drops, so let's establish them by starting at the negative terminal of the battery and going in a counterclockwise direction. That is the direction of the electron-flow, you will recall. This would make the end of R_1 nearest to the battery <u>negative</u>, wouldn't it? The polarities, then, would be like this.

Fig.: XIII-5-2

Let's start the equation.

$$-E_{R_1} - E_{R_2} - E_{R_3} + E_{applied} = 0$$

$$\text{or } -I_1 (R_1) - I_1 (R_2) - I_1 (R_3) + E_{applied} = 0$$

Where did we get the minus signs? You will notice that, starting at the negative terminal of the battery and going around the circuit in a counterclockwise direction, and stopping when we get back to where we started, we give the polarity we find at the <u>near</u> end of the voltage drops and at the applied voltage. Let's look at it again while studying the circuit - and knowing what each figure represents and why the sign is as it is.

15152

$$-I_1(R_1) - I_1(R_2) - I_1(R_3) + E_a = 0$$

$$-7(R_1) - 7(R_2) - 7(R_3) + E_a = 0$$

$$-7(4) - 7(6) - 7(5) + 105 = 0$$

$$-28 - 42 - 35 + 105 = 0$$

In writing the equation, you can start anywhere you please and go in either direction. It is best, however, to be consistent in starting points; and, if possible, make your starting point at the negative terminal of the source voltage. Forming this habit will be helpful later on when you will be writing equations for more complex circuits.

To illustrate how you can start at another place and go in the other direction, let's do just that with the circuit we have just studied.

Fig.: XIII-5-3

Let's start at point S and go in a clockwise direction.

$$I_1(R_2) + I_1(R_4) - E_a + I_1(R_3) = 0$$

$$7(6) + 7(4) - 105 + 35 = 0$$

$$42 + 28 - 105 + 35 = 0$$

$$105 - 105 + 0$$

15153

ASSIGNMENT:

Write the Kirchhoff's-Law equations for the following circuits.

1

2

3

4

UNIT XIII - KIRCHHOFF'S LAWS

Lesson No. 6 — Two Voltage Sources

There will be occasions in your electrical work when you will run into circuits having two different voltage sources. Study the one below and see if you can solve for I_1, I_2, and I_3, using Ohm's Law.

Fig.: XIII-6-1

Now that you have learned that Ohm's Law will not help you get the answers, let's see how it can be solved.

There are three different currents in this circuit. We shall first study the one from E_1 going through R_1, R_5, and R_4 back through E_1, and we'll call it I_1. Similarly, E_2 can force a current through R_2, R_5, and R_3. We'll call this current I_2.

Have you noticed that both I_1 and I_2 go through R_5? We'll call the sum of these two currents I_3, and remember that $I_3 = \Sigma\ (I_1 + I_2)$.
I_1 may be going in one direction while I_2 could be going in the other direction. This is why we add the two currents <u>algebraically</u>. The Greek letter sigma (Σ) means the <u>algebraic sum of</u>.

For example, if $I_1 = 5A$ and $I_2 = -3A$, I_3 could be found like this:

$$I_3 = \Sigma\ (I_1 + I_2)$$
$$I_3 = 5 + (-3)$$
$$I_3 = 5 - 3$$
$$I_3 = 2A$$

Let's write the equation for the left side of the above circuit.

15155

$$-E_{R_1} - E_{R_5} - E_{R_4} + 10 = 0$$

$$-I_1 (R_1) - I_3 (R_5) - I_1 (R_4) + 10 = 0$$

Don't forget that the current going through R_5 is I_3 and $I_3 = \Sigma (I_1 + I_2)$

$$- I_1 (4) - (I_1 + I_2) 6 - I_1 (2) + 10 = 0$$

$$- 4I_1 - 6 I_1 - 6I_2 - 2 I_1 + 10 = 0$$

We can combine all the I_1's. We get

$$\text{(A)} - 12I_1 - 6I_2 + 10 = 0$$

That is all we can do with this equation at this time, so let's call it <u>Equation A</u> and leave it for now while we go back and develop the equation for the right side of the circuit.

$$-E_{R_2} -E_{R_5} -E_{R_3} + 10 = 0$$

$$-I_2R_2 - I_3R_5 - I_2R_3 + 10 = 0$$

$$-I_2(4) - (I_1 + I_2) 6 - I_2(4) + 10 = 0$$

$$-4I_2 - 6I_1 - 6I_2 - 4I_2 + 10 = 0$$

Combining all the I_2's, we get

$$\text{(B)} -6I_1 - 14I_2 + 10 = 0$$

If we had a simple equation like

$$5I_1 - 10 = 0$$

by the rules of algebra it would be easy to find out the value of our unknown quantity, I_1. First we would add 10 to each side of the equation. (This does not change the truth of the equation.)

$$5I_1 - 10 + 10 = 0 + 10$$

or $$5I_1 = 10$$

There is another trick we can perform now, to help us find I_1. It doesn't change the truth of the equation either. We divide both sides of the equation by the number 5.

15156

218 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

$$\frac{5I_1}{5} = \frac{10}{5}$$

or $$I_1 = 2$$

That is how we would go about solving a simple equation that has one unknown quantity in it.

If we look at equations A and B, however, we find that each contains <u>two</u> unknown quantities-- I_1 and I_2. Neither equation, taken by itself, can enable us to find their values. However, we can work with these two equations together, and find the unknown quantities. When we work with two equations in this manner, they are called <u>simultaneous equations</u>, because we work with both at the same time - or <u>simultaneously</u>.

Let's place one of these equations over the other, as if to add them.

(A) $$-12I_1 - 6I_2 + 10 = 0$$

(B) $$-6I_1 - 14I_2 + 10 = 0$$

If we had the same number of I_1's or I_2's in each equation, we could perform a simple trick to find one or the other - we could add or subtract the two equations. This would leave us with only one unknown quantity, which would make a solution possible.

So let us multiply equation B by -2. This will not change the truth of the equation. That will give us $+12I_1$ which will cancel out the $-12I_1$ if we add equation B to equation A.

But remember, if you multiply equation B by -2, you must multiply the <u>entire</u> equation — everything on both sides of the = sign — so that it is still true.

$$(-2) \times -6I_1 - 14I_2 + 10 = 0$$

will give $$+12I_1 + 28I_2 - 20 = 0$$

Now add the two equations, A and the new form of B.

$$\begin{array}{lrrrl} (B) \times (-2) & \cancel{12I_1} & + 28I_2 & - 20 & = 0 \\ (A) & \cancel{-12I_1} & - 6I_2 & + 10 & = 0 \\ \hline & & 22I_2 & - 10 & = 0 \end{array}$$

15157

218

$$+22I_2 = +10 \text{ (adding 10 to both sides)}$$

$$I_2 = \frac{10}{22} \text{ (dividing both sides by 22)}$$

$$\text{or} \quad I_2 = 0.454\text{A}$$

We could take this newly found value of I_2 and substitute it for I_2 in either equation, A or B. That would leave I_1 as the only unknown value in the equation, making it possible to solve for I_1. This method is called the substitution method.

To be sure and safe, however, it is best to solve for I_1 just as we solved for I_2.

If we multiply equation A by 7 and equation B by -3, it will give values of I_2 in the two equations which will cancel out when the two equations are added.

(A) $-12I_1 - 6I_2 + 10 = 0$; x(7) gives $-84I_1 - \cancel{42I_2} + 70 = 0$

(B) $-6I_1 - 14I_2 + 10 = 0$; x(-3) gives $+18I_1 + \cancel{42I_2} - 30 = 0$

$$-66I_1 \qquad + 40 = 0$$

(Subtracting 40 from both sides) $-66I_1 = -40$

(Multiplying both sides by -1) $66I_1 = 40$

(Dividing both sides by 66) $I_1 = \frac{40}{66}$

$$\text{or} \quad I_1 = 0.606\text{A}$$

Now let's go back and solve for I_1 by the substitution method.

I_2 was found to be 0.454 A.

Let's plug this numerical value of I_2 into equation B. It will work, however, in either equation A or equation B.

15158

(B) $-6I_1 - 14I_2 + 10 = 0$

$-6I_1 - 14(0.454) + 10 = 0$

$-6I_1 - 6.356 + 10 = 0$

$-6I_1 + 3.644 = 0$

$-6I_1 = -3.644$ (subtracting 3.644 from both sides)

$I_1 = \frac{3.644}{6} = 0.607$ Ampere (Dividing through by -6)

It proves, doesn't it? It always will, if you are careful with your signs and watch your decimals.

Finding I_3 is now simple.

$$I_3 = \Sigma(I_1 + I_2)$$

$$I_3 = 0.606 + 0.454 = 1.060 \text{ amperes}$$

I_3 is the current we would have to use to find the value of E_{R_5}.

$$E_{R_5} = I_3 \times R_5$$

$$E_{R_5} = 1.06 \times 6 = 6.36 \text{ volts}$$

UNIT XIV - MAGNETISM

Lesson No. 1 — Legend, the Earth, the Compass

When you were quite young - even before you started to kindergarten- you probably enjoyed playing with magnets. Perhaps you had little magnetized toys. Well, many years ago - in fact, thousands of years ago - grown men, gray-headed scholars, played with magnets and pondered the reasons for their strange actions. Today, scientists are still playing with magnets and they are unlocking some of the many secrets still unknown about magnetism.

Before the beginning of the Christian era, men found small pieces of iron ore near the town of Magnesia in Asia Minor. They found that this peculiar ore would attract pieces of iron. The ore (or stone) was called magnetite because it was discovered near Magnesia, and the name magnet comes from magnetite.

You can imagine what a strange thing a magnet was in that day when a man had none of the marvels of science and electricity around him. It is easy to understand how these people let their imaginations run away with them. Today we can read the stories which they made up during their excitement about the powers of magnetism. They made up tales about certain islands of magnetite drawing the nails out of ships, reducing them to nothing but boards floundering around on the sea!

It was many years later, however, when man discovered that he could make an artificial magnet by rubbing a strip of iron with a piece of magnetite.

Fig.: XIV-1-1

15161

Still more years later, man learned that if he suspended a bar magnet on a string, it would come to rest with a certain end pointing to the north and the other end toward the south.

Fig.: XIV-1-2

He already knew that magnets had "poles" - that is, ends which were opposite to each other in their force. If he had two bar magnets, the end of one would attract one end of the other and would repel the other end. It seems logical, then, that he came to the conclusion that the earth was something like a magnet itself. This discovery was perhaps one of the greatest in the history of mankind, because of its aid to sea navigation.

To avoid confusion, the poles of a magnet are labeled. One end always seeks the north pole of the earth, and so it is called the north pole of the magnet. The other end (that seeks the south) is called the south pole of the magnet.

If a bar magnet is placed under a piece of glass, and iron filings sprinkled on top of the glass, these filings will line up as shown in the following photograph.

Fig.: XIV-1-3

5'62

We know that there is power here which can force particles of iron to move, and it is seen here that this force is concentrated in lines. Therefore it remains to decide in which direction these lines travel. Scientists have agreed to accept the direction as running from the north pole to the south pole of the magnet outside the magnet (and continuing inside the magnet from the south pole to the north). So we can say now that the stronger the magnet, the more lines of force we will have; also that these lines run from the north pole to the south pole of the magnet.

The total number of magnetic lines of force through a given cross section (of a magnet or magnetic field) is called the magnetic flux.

It has been found that the magnetic lines of force never cross.

Magnetic lines of force are always in closed loops. They seem to form complete circuits outside and inside the magnet, through its poles.

Magnetic lines coming from the same pole tend to repel one another. Another way of saying this is that lines of force traveling in the same direction (convention assumes they move) repel one another.

Magnetic lines will pass through all kinds of materials, whether they are magnetic materials or not. So there cannot be a magnetic insulator.

Knowing the above four facts, along with the knowledge that like poles repel and unlike poles attract, scientists have been able to employ magnetism in the performance of many duties.

Magnetism possesses secrets yet unsolved. Scientists have not fully explained this mysterious force. The modern theory of magnetism is that a magnetic material becomes a magnet when the atoms in that material are made to become aligned instead of being in their original random positions. What makes them become aligned?

The magnetic alignment is caused by the electrons of the magnetic material. The movements of electrons always create magnetic fields.

Magnetic materials have an uneven number of electrons in certain orbits. Electrons tend to form pairs. These pairs spin in opposite directions. Since a magnetic field is caused by the spin movement, their magnetism is thus cancelled. But an uneven number of electrons does not allow one electron to form a pair. The unbalanced spin of that electron causes an atom to have a magnetic field.

15163

When an external magnetic field, such as a bar magnet, is brought into contact with the randomly arranged atomic fields, the atomic fields rearrange themselves so that they are parallel with the stronger external field.

A representation of randomly arranged atoms in an unmagnetized substance.

Fig.: XIV-1-4

A representation of aligned atoms in a magnetized substance.

Fig.: XIV-1-5

Iron and metals containing considerable proportions or iron are among the better magnetic materials - materials that can be attracted by magnets and can themselves be made into magnets. Soft iron can be easily magnetized and can also be easily demagnetized. Such materials are known as temporary magnets when they are magnetized. Many of our so-called "permanent" magnets are made of steel. One of the strongest is known as Cast Alnico V, which contains aluminum, nickel, cobalt, copper, and iron. Permanent magnets have many uses in electricity and electronics. Practically all loudspeakers today have strong permanent magnets in them.

Magnets should never be heated or dropped. Heat or a sharp jarring knocks the molecules out of line, and the material returns to its original condition with random-positioned molecules. Horseshoe-type magnets should be kept with a "keeper" across the open poles. This keeper can be made of any piece of iron or steel.

QUESTIONS:

1. What is magnetite?

2. How did the magnet get its name?

3. Give three precautions for preserving the strength of a permanent magnet.

4. What is the molecular theory of magnetism?

5. What are the metals in Cast Alnico V?

15164

UNIT XIV - MAGNETISM

Lesson No. 2 Electromagnetism

In 1777, the year after the signing of the Declaration of Independence, Hans Cristian Oersted was born in Copenhagen, Denmark. By the age of 12 he was assisting his father in his apothecary, where he became interested in chemistry. He entered the University of Copenhagen at the age of 17 and received a medical degree after 6 years of study. He did not practice medicine for long. Six years after graduation he was back at the university, this time as a professor of physics. On a certain day in 1819, when he had been teaching there 14 years, he was lecturing to a class when he by chance placed a wire carrying an electric current parallel to a compass needle. Much to his surprise, the needle swung around and pointed at the wire. When he reversed the current, the needle turned around so that its other end was pointing toward the wire!

It was on that day that man learned that there is a direct connection between electricity and magnetism. In time it became clear that there are lines of magnetic force around a conductor when it is conducting an electric current, and that the direction of the current determines the direction of the magnetic force.

In order to understand diagrams illustrating the direction of current flow, we must consider that we are looking at a cross section, or the end of the wire. If it has a cross on it like this

it means that the current is going <u>away</u> from the reader. (Think of the cross mark as the tail end of an arrow - the tail feathers.) If the end of the wire is shown with a dot in the center like this

it means that the current is coming <u>toward</u> the reader. (The dot represents the tip of the arrowhead, coming toward you.)

15165

The information you have learned in this lesson was thousands of years coming to man. Great scientists lost much sleep in pondering over the forces of magnetism and electricity, trying to decipher the puzzles - while you have learned this tremendous relationship in just a few minutes!

This relationship is vital to the study of electricity, because it forms the basis for the generation of electricity for commercial uses. It is important, too, in the understanding of motors, as well as thousands of other electrical and electronic components. You may not see the connection right now, but before long you will.

You know now that if a current flows through a conductor, a magnetic field will be created around that conductor. It is appropriate at this time to learn also that if a conductor is moved through a magnetic field, a voltage will be generated in the conductor, which can cause a current to flow if the circuit is complete. The experiment which follows this lesson demonstrates this interesting fact.

An important sidelight was postulated by Lenz and is now called Lenz's Law. This law states that when a current is induced in a conductor by a magnetic field, that current will flow in such direction that its magnetic field will oppose its inducing field. Using this law we can always find the direction of an induced current by using the left-hand rule.

QUESTIONS:

1. Who was Hans Christian Oersted?

2. What great discovery did Oersted make?

3. Was Oersted actually seeking the fact which he discovered?

4. Draw arrows indicating the direction of magnetic flux around this conductor.

5. Here are two conductors parallel to each other. Current is flowing through the left-hand one. Indicate the direction of the induced current and the induced magnetic field of the right-hand conductor.

6. Explain Lenz's law in your own words.

15167

UNIT XIV - MAGNETISM

Lesson No. 3 (Experiment) — Creating a Current-Flow with Magnetism

OBJECTIVE: To demonstrate (1) that moving a conductor through a magnetic field produces a voltage and (2) that there is a definite relationship between the direction of magnetic lines of force and the direction of current flow.

MATERIALS REQUIRED:

1 Galvanometer

1 3-ft. length of wire (meter lead or similar)

1 Strong horseshoe or similar permanent magnet

PROCEDURE:

1. Connect the 3-foot wire across the galvanometer terminals and bring that conductor down between the poles of the magnet, observing the direction of the needle's deflection on the meter.

2. Bring the wire back up through the magnetic field. Observe the direction of the needle's deflection again.

3. Increase the speed of movement through the magnetic field. Observe for change in maximum voltage.

4. At the same speed, cut through the magnetic field at an angle. Observe the difference in voltage magnitude.

5. Make several turns in the conductor and repeat steps 2 and 3, observing magnitude of the induced voltages.

15168

QUESTIONS:

1. Is there any difference in voltage magnitude when the conductor passes through the magnetic field at a faster rate of speed?

2. Why did the galvanometer needle deflect in the opposite direction when the lead was brought back up through the field in step 3?

3. Establish the direction of the current in the conductor when it came down through the magnetic field. Does it agree with what you have already learned about the direction of the lines of force?

4. In your notebook draw a picture of the magnet showing the direction of the lines between the poles. Show the conductor coming down through the field, and indicate the direction of current-flow through the conductor.

5. Repeat step 4, but showing the conductor going <u>up</u> through the field.

15169

PERFORMANCE OBJECTIVE STATEMENT

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYATEM

MILESTONE: I. STORAGE BATTERY

PERFORMANCE OBJECTIVE NO.: 1 TITLE: Remove, Clean, Test, and Replace Storage Battery

CONDITIONS:

BEHAVIOR:

25. If performance is satisfactory, clean and replace tools and materials
26. Remove fender covers and store in proper place
27. Close hood
28. Return automobile to proper parking area
29. Remove front seat covers and store in proper place
30. Clean work station for next project

PERFORMANCE CRITERIA:

To be able to service battery in 1 hour.

Learning time: 2 hours

1513

UNIT XIV - MAGNETISM

Lesson No. 4 Units

This is not the time for you to be given an entire course in magnetism, but if you progress in the field of electricity it will be necessary for you to eventually have a very good knowledge of magnetism. There are numerous formulas, ratios, and units represented by various Greek letters. This year, if you just get a basic understanding of only a small part of this study, you will find when you go on that you will have a good background on which to build your knowledge. So, be sure that you fully know the few things that are brought out in today's lesson.

MAGNETOMOTIVE FORCE (m.m.f.) is comparable to electromotive force in Ohm's-law formulas. The practical unit of m.m.f. is the ampere-turn abbreviated At. (In many physics books and engineering texts you will find another unit used - the gilbert, named in honor of Dr. William Gilbert, 1544-1603, scientist and physician. The gilbert is designated by the letter G, and is equal to .7958 ampere-turns.)

If 2 amperes of current are sent through a coil made up of 50 turns, the m.m.f. (magnetomotive force) will be 100 ampere-turns. If 8 amperes of current are sent through a coil made up of 100 turns, the m.m.f. will be 800 ampere-turns.

Magnetomotive force is the force set up by the current flowing through the coil. IT IS NOT A MEASUREMENT OF THE POWER OF THE ELECTRO-MAGNET. The strength of the magnet will depend also on the material in the core and its permeability.

PEAMEABILITY (μ) is a measure of a material's relative ability to conduct magnetic lines of force. When we say <u>relative</u> ability, we are comparing the material's ability to the ability of air to conduct those magnetic lines. Air is given a permeability of 1. Permeability is designated by the Greek letter <u>mu</u> (μ).

FLUX DENSITY (B) is the number of lines of magnetic flux per square centimeter. In some of the larger units it is the number per square meter or per square inch. Basically, however, flux density is the number of magnetic lines per square centimeter. The basic unit for flux is called <u>gauss</u>. The gauss is the cgs (centimeter-gram-second) unit. The term <u>tesla</u> has recently been given to the MKS (meter-kilogram-second) unit. The English unit is <u>kilolines per square inch</u>. Flux density is designated by the letter B.

15170

FIELD INTENSITY (H) is the magnetizing force per unit of length. It is the number of gilberts per centimeter of length of the material conducting the flux lines. This force is designated by the letter H. Sometimes it is just spoken of as magnetizing force.

The relationship of μ, B, and H can be seen in the mathematically expressed ratio

$$\mu = \frac{B}{H}$$

This formula can be re-arranged just as in Ohm's-law formulas.

$$\text{If } \mu = \frac{B}{H}, \text{ then } H = \frac{B}{\mu}, \text{ and } B = \mu H$$

ASSIGNMENT:

1. Who was William Gilbert? (It is suggested that you refer to a good encyclopedia and learn something about this man.)

2. Of what is the gilbert the unit of measurement?

3. In the study of magnetism, what does the letter B denote?

4. What does H denote?

5. What is an ampere-turn?

6. If a coil of 200 turns has 6 amperes flowing through it, what is its magnetomotive force?

5.71

15170

UNIT XV - METER MOVEMENTS

Lesson No. 1 — The Basic Movement

When most young men learn to drive automibiles, they do so before they learn what makes the car go. They know how to start the engine. They get the feel of the steering wheel, and learn the functions of the instruments and controls, but at first few of them know the functions of the valve lifters or the high-speed jet. You have recently learned how to make measurements with a VOM. By now, surely, your curiosity is demanding that you know what is inside the meter case.

The heart of the meter is the meter movement. It may be an ohmmeter, a d-c voltmeter, an a-c voltmeter, or an ammeter, and still have the same kind of basic meter movement.

In your study of magnetism you learned that, by moving a conductor through a magnetic field, you can produce an electric current. It is also true that, if an electric current is flowing through a conductor that is free to move in a magnetic field, the conductor will move due to its own magnetic flux set up by that current flow. It works both ways, you remember: a moving conductor can cause a current-flow, and a current-flow can cause a conductor to move.

In applications of both of these principles, coils of wires are used rather than simple conductors. In the first situation mentioned above, the more turns the coil of wire has as it moves through the magnetic field, the more current will be produced. Also, on the other hand, a given amount of current can cause greater movement of a coil with many turns than of a coil with only few turns.

If current is run through a coil which is wound on a rotatable drum placed between the poles of a permanent magnet, the drum will turn in an attempt to line up the turns with the flux between the poles of the magnet.

15172

Figure XV-1-1 shows how a conductor tends to line up with the magnetic lines of force.

Fig.: XV-1-1

A. Current flowing through coil sets up magnetic flux opposing flux of permanent magnet.

B. Coil rotates toward unopposed position.

If a pointer is connected to a coil of wire - or to the drum or cylinder upon which the coil is wound, it will point to any value printed on any scale placed under the pointer. If you constructed such a piece of apparatus with the correct number of turns and the magnetic field of such strength that the pointer would point to its maximum position when one milliampere of current was flowing through the coil, you would have a one-milliampere meter movement. If you ran a weaker current through the coil and the pointer came to rest at a point exactly midway on the scale, you would know that there was half as much current as that one milliampere which gave full-wave deflection. So the new current would be 0.5 ampere.

15173

The most commonly used meter movement is constructed basically in this manner, and is called a moving-coil movement or a D'Arsonval movement. Many of our present movements are called Weston movements. This movement is simply a slightly modified D'Arsonval movement.

D'Arsonval Movement Fig.: XV-1-2

15174

Figure 3 shows more detail in the construction of the basic D'Arsonval movement, and Figure 4 shows the movement's location within the meter.

Details of Basic D'Arsonval Movement

Fig.: XV-1-3

15175

D'Arsonval Movement in Case with Scale

Fig.: XV-1-4

Note that the spring holds the pointer at the zero position.

QUESTIONS:

1. The moving-coil movement is known by two other names. What are they?

2. Is the basic moving-coil meter movement used in voltmeters, in ohmmeters, or in ammeters?

3. When there is no current flowing in the coil of the basic meter movement, which way are the turns of the coil in respect to the magnetic flux from the poles of the magnet - parallel to the lines of force or at an angle to them?

15176

UNIT XV - METER MOVEMENTS

Lesson No. 2 Other Movements

Besides the D'Arsonval movement there are other movements. Some of them are better suited for their special kinds of measurements; and even though we shall be using D'Arsonval movements more than any other kind, we should know something about the others.

The ELECTRODYNAMOMETER-type movement is often used in a.c. measurements. It is not necessary to change the alternating current to direct current to activate this movement, as must be done in the D'Arsonval movement.

Where the D'Arsonval movement had a single coil moving in the magnetic field of a permanent magnet, the electrodynamometer-type movement has another coil. In fact, there are four coils - two movable coils arranged so as to be able to rotate between two fixed coils. Here again the principle is that which causes two conductors with magnetic fields to tend to align themselves.

Inside construction of an electrodynamometer.

Fig.: XV-2-1

15177

Figure 2 shows the circuit arrangement of the electrodynamometer-type meter.

Circuit arrangement of electrodynamometer type meter

Fig.: XV-2-2

The dynamometer-type movement is less sensitive than the moving-coil-type (the D'Arsonval) movement. However, it is very accurate, and is used in a.c. applications.

THE IRON-VANE-TYPE MOVEMENT

If two pieces of soft iron are placed in a coil through which an electric current is flowing, the two pieces of iron will become magnetized - each having its south pole next to the south pole of the other, and its north pole next to the north pole of the other. Since unlike poles attract and like poles repel, the pieces of iron are going to push away from each other, as is shown in Figure 3.

Principle of Iron-Vane Meter Movement Operation

Fig.: XV-2-3

15178

You will notice that, regardless of the direction of current flow, the action will be the same. This means, of course, that this meter movement will operate with a.c. without its having to be changed to d.c.

Figure 4 is a simple illustration of one type of iron-vane meter movement.

Fig.: XV-2-4

The pointers on most meter movements move in proportion to the amount of current flowing through them. The scales are linear - that is, each time the current is increased by a particular amount, the movement will increase by the same amount. This is not so with the iron-vane-type movement. As the current is increased, the pointer deflection increases by the square of the amount of current increase. This type scale is called a square-law scale.

Typical Square-Law Iron-Vane Meter Scale

Fig.: XV-2-5

QUESTIONS:

1. Is it necessary to have a rectifier in a meter utilizing the electrodynamometer movement?

2. How many coils are there in the electrodynamometer movement?

3. Is the D'Arsonval movement as sensitive as the electrodynamometer movement?

4. Is the electrodynamometer movement current-operated or it is voltage-operated?

5. Is the electrodynamometer an accurate movement?

6. What is the principle of the operation of the iron-vane-type meter movement?

7. How does the scale of the iron-vane-type movement differ from that of the common D'Arsonval movement?

15180

UNIT XV - METER MOVEMENTS

Lesson No. 3 Other Movements (II)

Sometimes it is necessary to measure very high voltages, like those found in television picture tubes and the anode voltages in x-ray tubes. Sometimes it is necessary to have as much as 100,000 volts present in x-ray tubes. To measure these high voltages we often find ELECTROSTATIC voltmeters used.

In the study of electrostatics it was noted that when two pith balls are given like charges, they repel each other, and when given unlike charges they attract each other. The electrostatic voltmeter operates on this principle. The main operating parts in this type of movement are the two plates which are connected to the potential differences - that is, one plate is connected to one terminal of the voltage to be measured and the other plate is connected to the other terminal. The plates are arranged so that one is stationary while the other is permitted to move according to the force of the charge. The movable plate is so connected to the pointer that it will indicate the voltage on a scale. Figure 1 demonstrates the action of this meter movement.

Principle of Electrostatic Voltmeter with Non-Linear Scale

Fig.: XV-3-1

Since there is no electrical connection between the plates in this meter, it is ideal for measuring voltages where the drawing of current would load the circuit. This type of movement is different from all others in that is is voltage-operated rather than current-operated.

The scale of the electrostatic movement is non-linear.

15181

Another type of meter should be discussed here. It is known as the THERMOCOUPLE AMMETER. ("Thermo" means heat and "couple" is a linking together) The basic movement is the D'Arsonval movement. This type of meter works on two principles:

1. Heat is produced by the flow of electric current.

2. When certain dissimilar metals are joined together and heated, a voltage is produced.

There are several physical arrangements of thermocouple and heater elements used. Figure 2 shows the way this meter works.

Fig. XV-3-2

The heat produced within the nichrome resistance element by the current heats the junction of a copper bar and a constantan bar. Constantan, an alloy often used in thermocouples, consists of 60% copper and 40% nickel.

These heat-activated meters are often used in measuring very high frequency voltages, such as in radio transmitters and in radar. You may hear them called <u>bolometers</u> or sometimes <u>barretters</u>.

QUESTIONS:

1. Where would it be practical to use an electrostatic voltmeter?

2. What is a bolometer?

3. Is the electrostatic voltmeter a current-operated device?

4. Is the thermocouple ammeter a current-operated device?

5. Does the electrostatic voltmeter have a linear scale?

15182

UNIT XV - METER MOVEMENTS

Lesson No. 4 — The Voltmeter

The moving-coil-type meter movement, as you know, is a current-operated device. On the other hand, it is known that the coil in that movement has a certain amount of resistance, and when current flows through a resistance, a voltage is developed across it. There is a direct relationship between the meter's pointer deflection and that voltage drop across the coil.

If a meter movement has a sensitivity of 50 milliamperes (0.050 amperes), that is the amount of current necessary to give full-scale deflection. If the coil resistance is 20 ohms, we can find the voltage developed across the coil by using Ohm's Law:

$$E = I \times R$$

$$E = 0.050 \times 20 = 1 \text{ volt}$$

If we wish that movement to measure 10 volts, we could not apply it right across the meter terminals. We would have to lose 9 volts somewhere. This is done by placing an additional resistor in the circuit. This is called a multiplier resistor.

To know what value of multiplier resistor is needed, the first information needed is just how much <u>total</u> resistance is desired in the circuit. To find R_t, the following formula is used:

$$R_t = \frac{E_{full\ scale}}{I_{full\ scale}}$$

$$R_t = \frac{10}{0.05} = 200 \text{ ohms}$$

If R_t is 200 ohms, and the moving coil itself has 20 ohms, it is simple to understand that all one has to do now is to subtract the meter resistance from the total resistance. We would have

$$R_{multiplier} = R_t - R_{meter\ movement}$$

15183

15183

Perhaps it would be better to write all of it in one formula:

$$R_{multiplier} = \frac{E_{full\ scale}}{I_{full\ scale}} - R_{meter\ movement}$$

A multirange voltmeter can be constructed by placing a number of multiplier resistors in the circuit and making arrangements to switch from one to another, as shown in Figure 1.

Simplified voltmeter circuit.

Fig.: XV-4-1

15184

Multirange Voltmeter Using Fixed-Tapped Resistor

Fig.: XV-4-2

A multirange voltmeter can also be constructed by using various taps on a single resistor, as shown in Figure 2.

The sensitivity of a voltmeter is rated in ohms per volt. This is the amount of resistance (in ohms) necessary to have the needle show full-scale deflection when 1 volt is applied. A good voltmeter has high sensitivity. A 5000-ohms-per-volt voltmeter is not considered a very good meter for making certain measurements. A meter such as this has a decided loading effect and can result in lowering the voltage by measuring it. In purchasing a voltmeter, it is best to get one with a 20,000-ohm-per-volt sensitivity. Where even higher sensitivity is needed, it is best to use a vacuum tube voltmeter, which will be discussed later.

QUESTIONS:

1. How is the sensitivity of a meter movement rated?

2. How is the sensitivity of a voltmeter rated?

3. Why is it best to use voltmeters of high ohms-per-volt rating?

4. What is a multiplier resistor?

5. If you have a meter movement which has an internal resistance of 50 ohms and a sensitivity of 25 milliamperes, and you want to design a voltmeter which will measure 10 volts, what would be the value of the multiplier resistor?
   Make this calculation and draw the circuit in your notebook.

6. Suppose you wish this meter to have both a 10-volt range and a 100-volt range. Make the calculation for the multiplier resistor and draw the diagram of this two-range meter in your notebook.

UNIT XV - METER MOVEMENTS

Lesson No. 5 — The Ammeter

A simple meter movement is an ammeter in itself. A 50-microampere movement will measure currents from 0 to 50 microamperes. On an ordinary moving-coil movement, 25 microamperes would deflect the pointing needle halfway across the scale on a 50-microampere movement. A current of 100 microamperes would probably damage the movement mentioned above. Suppose, then, you wanted to measure currents up to 100 microamperes. Doesn't it stand to reason that if you bypass half of this current, 100 microamperes would then show full-scale deflection on the meter (since it would have only half of the 100 microamperes going through the meter)?

If you are bypassing half of the current in the above meter arrangement, and you cut the 100 microamperes down to 50 microamperes, that will permit 25 microamperes to pass through the movement and show half-scale deflection.

When you wish to measure the current flowing in a circuit, you place the meter in series with the circuit as shown here:

Connection of Ammeter to Circuit

Fig.: IV-5-1

15'86

Basic Multirange Ammeter

Fig.: XV-5-2

Instead of having to connect the bypass (shunt) resistors on the outside of the meter case, it (or they) can be placed inside the case and switched in and out as the need for different ranges occurs. Figure 2 shows such an arrangement.

If you had a meter movement with a sensitivity of 1 milliampere and an internal resistance of 50 ohms and wanted to be able to measure currents up to 10 milliamperes, you would use this equation to calculate the shunt resistance:

$$R_s = \frac{E_s}{I_s}$$

First you need to find the value of the shunt current (I_s).

$$I_s = I_t - I_m$$

This is easy, since you know that the total current will be 10 milliamperes, and you know that the meter current cannot be over 1 milliampere. So

$$I_s = I_t - I_m$$

$$= 10 \text{ MA} - 1 \text{ MA} = 9 \text{ MA}$$

Next you need to find E_s. This is the voltage across the shunt resistor which, of course, must be the voltage across the meter movement—since they are in parallel. So

$$E_s = E_m = I_m \times R_m$$

$$= 0.001 \times 50$$

Now that you have the values for E_s and for I_s, you can plug them into the first formula:

$$R_s = \frac{E_s}{I_s} = \frac{0.001 \times 50}{0.009} = 5.55 \text{ ohms}$$

15187

ASSIGNMENT:

1. In your notebook draw a diagram showing an ammeter placed in a circuit in such a way that the current in the circuit may be measured.

2. Draw another diagram showing a meter movement in a circuit where it is measuring current, and in this diagram show a shunt resistor.

3. Suppose the meter movement in No. 2 has an internal resistance of 45 ohms and has a sensitivity of 1 milliampere. Find the value of the shunt resistor (R_s) if it is desired to measure up to 100 milliamperes.

15188

15188

UNIT XV - METER MOVEMENTS

Lesson No. 6 — The Ohmmeter

The ohmmeter consists of a meter movement (usually the D'Arsonval movement), a battery, and a known value of resistance. Basically, a series ohmmeter operates in the manner indicated in the following schematic diagram:

Schematic drawing of a series ohmmeter

Fig. XV-6-1

Let us assume that the battery produces 1 volt and that the resistance is 1000 ohms.

$$I = \frac{E}{R} = \frac{1}{1000} = 0.001 \text{ A} = 1 \text{ MA}$$

The meter movement being a 1-milliampere movement, 1 milliampere will cause full-scale deflection. Any value of resistance placed at point X will be in series with the 1 K-ohm known resistance, and will increase the total resistance of the circuit and lessen the current. If another 1 K-ohm resistor is placed at point X, the overall resistance will be 2 K-ohms. What will the current be?

$$I = \frac{E}{R} = \frac{1}{2000} = 0.5 \times 10^{-3} = 0.5 \text{ MA}$$

The current will be just half the original, and the needle will deflect to half-scale.

Let us look at the results. In the original condition, where there was no resistance placed at point X and the indicating needle was at full-scale, the resistance at point X was 0 ohms. So we can label the full-scale position "0".

Fig.: XV-6-2

The point X represents where the test leads are connected across a resistance in the circuit. So we can now say <u>when we connect the test leads to a 1 K-ohm resistor, the needle deflects half-scale</u>. We can label this point "1 K-ohm".

Fig.: XV-6-3

15190

Suppose we put the probes across a 500-ohm resistor instead of the 1 K-ohm resistor. This will add 500 ohms in series to the original 1 K-ohm resistance in the circuit, making the total resistance 1500 ohms.

$$I = \frac{E}{R} = \frac{1}{1500} = 0.666 \times 10^{-3} = 0.666 \text{ MA}$$

We can count off six and two-thirds of the 10 major divisions on the scale (actually two-thirds of full-scale), and label this point 500 ohms or 0.5 K-ohms.

Fig.: XV-6-4

Now let's replace the 500-ohm resistor with a 2000-ohm resistor. (Remember, we still have the 1000-ohm resistor in the circuit.)

$$I = \frac{E}{R} = \frac{1}{3000} = 0.333 \times 10^{-3} = 0.333 \text{ MA}$$

This would deflect the needle one-third of full-scale, and the point can be labeled 2 K-ohms.

Fig.: XV-6-5

15191

Study the scale we have just completed. You can see that the distance between 0 and 1 K-ohm is greater than the distance between 1 K-ohm and 2 K-ohms. (The higher the resistance-values go on the scale, the shorter will be the distance between each succeeding step. This goes on and on into infinity. That is the nature of electrical resistance of materials. Remember, there is no such thing as a perfect insulator. A perfect insulator would reduce the current to zero. Note that the high-resistance end of the scale ends with the sign of infinity—∞.

The following scale is the completed scale for one type of ohmmeter. Resistances, like voltages, can be measured on meters using various scales. Additional resistance can be put into the internal circuit to make it possible to measure high values of resistance with greater accuracy.

One value of resistance may be calculated so that the scale can be multiplied by 10, another by 100, 1000, and even up to 1,000,000.

Fig.: XV-6-6

By looking at the above, it is easy to see how a resistance near the 100 K-ohm end of the scale could be measured far more accurately if the scale had a R X 1000 multiplier. The needle would then be near 100 instead of being at the extreme high end of the scale, where just a hair's breadth would represent a much greater difference than at 100.

15192

QUESTIONS:

1. Is the scale on an ohmmeter linear?

2. Is the ohmmeter a current-operated or a voltage-operated device?

3. Why is it necessary to have a battery in an ohmmeter?

4. Calculate the currents that would flow through a 10 MA meter movement from a 1-volt battery when the following resistances are in the circuit: (For practical purposes you may forget that there is any resistance in the meter movement.)

   (a) 1000 ohms

   (b) 1500 ohms

   (c) 2000 ohms

   (d) 3000 ohms

   (e) 4000 ohms

   (f) 10,000 ohms

Indicate each value of resistance on the following scale.

15193

UNIT XV - METER MOVEMENTS

Lesson No. 7 — The Shunt Ohmmeter

On some of the voltohmmeters you will see around the shop, you will see a "Low Ohms" position on the function switch. You have already been told that you are never to leave the switch on this position. From this lesson you will understand why.

First, let us look at the schematic diagram of the shunt-type ohmmeter. This is the circuit made within your VOM when you switch it to "Low Ohms."

Typical Shunt-Type Ohmmeter Circuit

Fig.: XV-7-1

It can be seen that, with nothing across the test leads, there is current flowing in the circuit. Part of it is going through R_S, and the rest of it is going through the meter movement. If a resistor to be measured (R_X) is placed across the test leads, another path is made for current flow. Therefore, less current will flow through the meter movement.

15194

In the series ohmmeter, the movement carried maximum current when the resistor being measured was of minimum value. Therefore the scale was read from right to left. In the shunt-type ohmmeter, the movement carries maximum current when the resistor being measured is of maximum value. Therefore the shunt-type ohmmeter is read from left to right. Just to remember these differences is not enough. Study the two circuits and understand why one is read in one direction and the other is read in the opposite direction.

The shunt ohmmeter is usually used for measuring low values of resistance.

ASSIGNMENT:

1. If the test leads are not connected to anything, will the needle of the shunt-type ohmmeter deflect?

2. Why do we not leave the VOM switched to "Low Ohms"?

3. Compare the series-type ohmmeter with the shunt-type.

18195 12134

UNIT XV - METER MOVEMENTS

Lesson No. 8 — The Galvanometer

There are times when it is necessary to detect small values of electrical current and to determine the direction of those currents. The instrument used for this is the galvanometer, named in honor of Luigi Galvani, that Italian scientist of the 18th century who devoted much of his time to the study of electricity.

There are numerous types of galvanometers - from the rather inexpensive charge-discharge indicators one often finds on the instrument panels of sports cars to the very delicate and expensive beam-of-light types used in research laboratories.

Student galvanometer

Galvanometer for classroom demonstrations

Fig.: XV-8-1

15196

Research galvanometer

Fig.: XV-8-2

Most galvanometers have the conventional D'Arsonval movement. Shown above is an illustration showing one of the more sensitive galvanometers. Instead of the moving coil being supported by bearings or jewels, this type is suspended on flat ribbons of phospher bronze. There is practically no friction loss in this type. Losses are further reduced by eliminating the indicator needle with its spring. A small beam of light is reflected from a small mirror that turns with the coil assembly.

15197

Simplified diagram of a galvanometer

Fig.: XV-8-3

Most definitions of the galvanometer state that it indicates the direction of current. There is one special type, however, that is used for a.c. This is a very special type which is termed a galvanometer by a limited number of technicians and scientists.

QUESTIONS:

1. What type movement is usually found in galvanometers?

2. What is the advantage in using the beam of light and a mirror in galvanometers?

3. Give your definition of a galvanometer.

15198

UNIT XVI - MULTIMETERS

Lesson No. 1 Principles

There are many different kinds of multimeters. Many different manufacturers produce them. Regardless of how many sizes, shapes, or colors you might find, those used by servicemen and technicians fall into two classes - the VOM and the VTVM.

Vacuum-Tube Voltmeter
(VTVM)

Volt-Ohmmeter
(VOM)

Volt-Ohmmeter
(VOM)

15199

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: II. IGNITION SYSTEM- DISTRIBUTOR

PERFORMANCE OBJECTIVE NO.: 2 TITLE: Remove, Disassemble, Reassemble, Replace, and Adjust Distributor

CONDITIONS:

This assignment will be performed on a complete automobile.

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective cover on front seat of automobile
2. Move automobile into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper manual and turn to appropiate chapter
6. Select proper tools and materials
7. Disconnect battery ground cable
8. Remove air breather assembly
9. Disconnect vacuum line from distributor
10. Disconnect primary laed wire at coil
11. Unfasten distributor cap retaining clips and lift off the distributor cap
12. Rotate engine until distributor rotor is pointing towards center of engine fan
13. Mark this point on distributor housing and engine block (This is the reference points for installing the distributor

PERFORMANCE CRITERIA:

1510

The multimeter is several meters in one case, and there is a switch which permits switching from one meter to the other. It is done like this:

Fig.: XVI-1-2

Besides switching from one meter circuit to the other, special switching is done so that the same components may be used in more than one meter circuit; and, of course, the ranges must be changed to the range needed at the time. Rotary switches are used to do these jobs. A rotary switch usually has many connecting terminals

15200

and looks like this.

Fig.: XVI-1-3

Fig.: XVI-1-4

Sometimes all the connections are on one deck or "wafer," and sometimes there are numerous wafers. In many multimeters there are rotary switches with three wafers, which look like this.

So you can see how many different connections may be made or broken by moving just one position on a rotary switch.

On some rotary switches, there are contacts on each side of the wafers, making it possible for one wafer to act as two. This is the type of rotary switch used by the Philco Model 7005; individual circuits of this model will be discussed in some detail in this unit.

12500

15201

The d.c. voltmeter cirucit is rather conventional and follows the principles you have already studied. Study the function of all the components in this circuit (Fig. XVI-1-5) and be prepared to discuss them in class.

Fig.: XVI-1-5 *D-C Voltmeter Circuit*

15202

If you will now study the diagram of the a.c. voltmeter circuit (Fig. 6), you will find that it has a rectifier (CR-1) in series with

Fig.: XVI-1-6 *A-C Voltmeter Circuit*

15203

15203

the line to the meter movement. The movement (the D'Arsonval, in most cases) is operated by direct current. Alternating current would cause the needle to try to go first in one direction and then in the other, at the frequency of the current. With ordinary house current - 60 cycle a.c. - the needle would try to change direction 120 times per second. The rectifier will pass the current in one direction only, so, actually, the current is flowing in the meter for only half the time. The circuit is so designed and the time that the current is off is so short that the needle remains steady and indicates the correct voltage.

Ask your shop instructor to show you several different types of rotary switches. Ask him to include one which has at least one wafer which has contacts on both sides. Examine these carefully, especially the wipers (the moving contacts). You will find that some of them are double, some make contact with more than one of the stationary contacts at the same time, and some of them may have more than two separate moving contacts.

Also, ask your instructor to show you a meter rectifier and compare it with other rectifiers.

ASSIGNMENT:

On a large piece of paper draw the schematic for the d.c. voltmeter and the a.c. voltmeter. With a writing implement of another color, draw in a switch connecting to test jacks and switched into such a position as to have the jacks connected to the a.c. voltmeter.

15204

UNIT XVI - MULTIMETERS

Lesson No. 2 — The VOM

If you take the two circuits that we studied in the last lesson and add an ohmmeter and another circuit for measuring current you will have a voltohmmeter, or a VOM. Let us study the following ohmmeter circuit.

Fig.: XVI-2-1 *Ohmmeter Circuit Shown on the Rx100 Range*

15205

Why is R4 in the circuit? Just what does it do? If you cannot answer this, go back to the lesson on ohmmeters and study it again. Also, make sure you know what R21 and R23 do in the circuit.

Study the d.c. ammeter circuit shown in Fig. 2 You will notice that switching S2 from positons 6 through 9 puts different shunt resistors across the meter, changing it from 100 microamperes to 500 milliamperes in four steps. If you will redraw the circuit as a 100 MA meter, leaving out all components through which no current flows, it will help you understand this circuit. If you do not then fully understand, it is suggested that you draw it for the other three ranges, each time omitting those components which are not in use.

Fig.: XVI-2-2 *D-C Ammeter Circuit*

15206

The following circuit (Fig. 3) combines all four of the previously described circuits shown in this unit. All switches are shown in Position #1, making it a 1000-V d.c. voltmeter. It will be of great help to you if you will draw a schematic of this circuit, under these conditions, omitting all components not being used for this circuit. (See next page for a suggestion.)

Fig. XVI-2-3 *Philco Circuit Tester, Model 7005, Schematic Diagram*

(Hint: Trace the circuit on the schematic first. With a pencil, very lightly indicate that part of the circuit in use. Then draw your simplified circuit.)

The following is a picture of the meter containing all of the circuitry studied in this unit. It is one of the better voltohmmeters.

Typical Multimeter (Philco Circuit Tester; Model 7005)

Fig.: XVI-2-4

ASSIGNMENT:

The following 3 schematics of the Philco Model 7005 voltohmmeter are included for you to use in tracing the different circuits with a pencil. See the instructions below each one.

12510

UNIT XVI - MULTIMETERS

Lesson No. 3 The Vacuum-Tube Voltmeter

If you need to read voltages present on household applicances, power-supply voltages in radio equipment, and the majority of potential differences, you will find the common VOM (volt-ohm-meter) not only satisfactory but the best, since you do not have to plug this meter into an a.c. outlet. No voltage is needed to operate the voltmeter circuit except the voltage being measured; and it has its own self-contained battery to operate its ohmmeter circuit.

There are voltages, however, that cannot be measured by the VOM. Some voltage sources are so weak that they cannot force any appreciable amount of current. The signal voltage on the grid of a radio detector, for instance, is so feeble that if you were to connect a VOM to it, the voltage would become much lower due to the load of the meter. The vacuum-tube voltmeter is the instrument needed to measure such voltages. No electronics serviceman's workbench should be without one. It does not overload the circuit being tested because the meter movement is not put across it. The meter movement is powered by another source of voltage. The voltage being measured is simply present on the grid of a vacuum tube, as Fig. 1 shows.

Fig.: XVI-3-1

Let us assume we are testing for a voltage. When there is no input voltage present, electron-current will flow from the negative terminal of the battery through the vacuum tube from the cathode to the plate. From the plate it goes through the meter and back into the battery. The more current flows through the meter, the more it will deflect.

If the grid is made more negative than the cathode, the current through the tube will be lessened. (Remember, electrons are negative charges. Like charges repel. So if the grid becomes negative, it

15212

will tend to drive the electrons back toward the cathode, reducing the current-flow through the tube and the meter.)

On the other hand, if the grid is made more positive in respect to the cathode, it will attract electrons. In doing this it actually accelerates the electrons. Since it is attracting the electrons, it is reasonable for you to first think that the grid will absorb them. This is not true, however. The grid is actually a fine wire wound around the cathode (but not touching it). The electrons must pass between these windings before reaching the plate. There is so much more space between the turns of the grid wire than the space occupied by the wire itself that the electrons shoot right by the grid and are drawn to the plate by the high positive plate voltage. Therefore the current will increase through the tube and through the meter.

Fig.: XVI-3-2

REMEMBER: If the grid voltage is positive in respect to the cathode, plate current will increase. If the grid voltage is negative in respect to the cathode, the current will become less; and if this negative potential becomes great enough, it will stop the flow of current through the tube altogether.

A schematic diagram of the Eico Model 232 vacuum-tube voltmeter is included (Fig. 3) for the more ambitious student who wishes to spend a little extra time in tracing the circuitry for its different functions. Doing this, and drawing simplified diagrams of the individual circuits will certainly help anyone gain a better understanding of the VTVM. (HINT: The instructor might even be able to give some extra credit for this kind of work.)

QUESTIONS:

1. What is the main advantage the vacuum-tube voltmeter has over the common VOM?

2. How does the applied voltage (the voltage being measured) cause the needle of the meter movement to deflect?

3. From what electrode to what electrode in the vacuum tube do the electrons flow?

15213

All switch wafer sides shown as they appear looking from the front (shaft end) of the switch toward the rear. The rear side of each wafer is seen looking thru the wafer from the front.

Relays on all switch wafers shown in extreme counter-clockwise position.

UNIT XVII - AMATEUR RADIO LICENSING

Lesson No. 1 — The Novice Operator

HELPFUL INTRODUCTORY INFORMATION

When one goes into the ham shack of almost all American radio amateurs he will see a copy of The Radio Amateurs Handbook. This is known by many as the ham's bible. It is published by The American Radio Relay League, Newington, Conn., 06111.

The American Radio Relay League is an organization which is run by the amateur operators who are members. When you get your license you may become one of the thousands of members who are united to advance the art and the pleasure of amateur radio.

The handbook covers nearly every phase of amateur radio — receivers, transmitters, radio-teletype, sideband, frequency modulation, antenna systems, and general electronics theory. The American Radio Relay League (the ARRL) publishes about a dozen other books which you should find of interest. If this list cannot be found in your shop, the League will send you a list of information concerning their organization and publications.

In some vocational and technical schools it is felt that getting into amateur radio brings added interest to those students in the electrical and the electronics courses, especially to those in the electronics courses. In fact, some schools require that the freshman get a Novice Radio Amateur's license before going into his sophomore year.

Before the Federal Communications Commission (FCC) opened the Novice class, there was no easy way to get into Amateur Radio. The General class was the lowest class, and to get this class license the newcomer had to pass a much more complicated theory examination, and he had to pass a 13-word-per-minute code test in both sending and receiving.

15215

Now a beginner can get a Novice license by being able to send and receive 5 words per minute, along with passing an examination which will prove that he knows enough about communications laws and radio theory to operate a Novice radio station.

Any radio amateur, 21 years of age or older, who possesses a General class amateur license or higher, may give the code test to one who wants to take the Novice test. This volunteer examiner then writes to the Federal Communications Commission, 334-36 York Street, Gettysburg, Pennsylvania, 17325 and requests the examination forms. The examination is sent to the volunteer examiner, who supervises the applicant's taking the examination. When the applicant finishes the examination, he is to furnish the volunteer with an envelope and postage stamp for mailing the examination back to Gettysburg, where it is checked. If the applicant passes the examination, that information is passed on to Washington from Gettysburg. His license will be sent from Washington, D. C. If the examination is failed, the notification comes from Gettysburg, Pennsylvania.

The Novice Class license is good for only two years, whereas the higher class licenses are permanent (though requiring renewal every five years). The Novice Class license can never be renewed, because it was given only to help the beginner get into the field of amateur radio more easily than before the creation of this class of license. It is generally considered that if the Novice is not ready for a higher class license after two years, he isn't the person who would advance himself enough to operate in the crowded Amateur frequency bands anyway.

In order to lessen the likelihood that the Novice operator might cause interference where he shouldn't, he is limited in power to 75 watts, and his transmitting frequencies must be crystal controlled. The General Class operator, and those above that class, may operate at input powers up to 1,000 watts. The Novice is held to 75 watts because of the dangers of transmitting harmonics of the transmitting frequency. The General Class operator may use a variable-frequency oscillator, which permits him to move from one frequency to another by merely turning a dial. The Novice may not use a variable-frequency oscillator (a VFO) because, being less skilled, he is more likely to move outside of the permitted band of frequencies. Therefore, the Novice operator must control his frequency with a crystal, which is not variable.

QUESTIONS:

1. What is the highest input power a Novice operator is permitted to use?

2. Why are the Electronics students in some schools required to obtain a Novice Class Amateur Radio license?

3. With what must the Novice operator control his operating frequency?

15216

UNIT XVII - AMATEUR RADIO LICENSING

Lesson No. 2 — Novice Frequencies

The Novice Class operator is allotted frequencies in the 80-meter, the 40-meter, the 15-meter, and the 2-meter Radio Amateur bands. In the 80-meter band he may operate from 3700 kc. to 3750 kc. In the 40-meter band he is permitted to operate from 7150 kc. to 7200 kc. In the 15-meter band he may operate from 21.1 mc. to 21.25 mc. In the 2-meter band he may operate from 145 mc. to 147 mc.

From the beginning of the Novice Class license until fairly recently, the Novice operator had been permitted to operate "voice" in the 2-meter band. Now, however, all operations must be A1 Emission (telegraphy, continuous wave). Again, this rule change was for the benefit of the Novice. If the beginner is permitted to go on radio-telephone operation, it is possible that he might never bring his code-speed up to the 13-word-per-minute requirement for the General Class license.

In 1964, American electronics manufacturers began using the term hertz for cycles per second. In most of the other countries of the world this term was already in use. It honored H. R. Hertz, the German scientist who was the first to demonstrate wireless communication. Hertz is abbreviated Hz. Kilohertz is abbreviated KHz, and megahertz is MHz.

	1 hertz (Hz)	=	1 cycle per second
	1 kilohertz (KHz)	=	1,000 cycles per second
	1 megahertz (MHz)	=	1,000,000 cycles per second
Also	1 cps	=	1 Hz
	1 kc	=	1 KHz
	1 mc	=	1 MHz

Let's look at the Novice frequencies again as they are given in the different units.

The 80-Meter Band (Novice)

	3700	-	3750 kc
or	3.7	-	3.75 mc
or	3.7	-	3.75 MHz

15217 15216

The 40-Meter Band (Novice)

	7150	-	7200 kc
or	7.15	-	7.2 mc
or	7.15	-	7.2 MHz

The 15-Meter Band (Novice)

	21,100	-	21,250 kc
or	21.1	-	21.25 mc
or	21.1	-	21.25 MHz

The 2-Meter Band (Novice)

	145	-	147 mc
or	145	-	147 MHz

QUESTIONS:

1. Why is radiotelephone operation being terminated for the Novice operator in the 2-meter band?

2. Express 3700 kc in MHz.

3. Express 7160 kc in MHz.

4. Express 21,100 kc in mc.

5. Express 147 mc in MHz.

6. Name the different bands that the Novice Class operator may use to transmit radiotelegraph signals.

7. What is A1 emission?

15218

UNIT XVII - AMATEUR RADIO LICENSING

Lesson No. 3 — Legal Transmitter Power

It has previously been mentioned that the Novice Class radio amateur operator may not use more than 75 watts. This is a very important fact, and it is one of those facts that the FCC is particularly careful in testing an applicant about before a license is issued to him. You must know how to measure your power.

The FCC regulations are on <u>input</u> power, not <u>output</u> power. To measure it, you must be able to know the voltage on the plate or plates of the final amplifier as well as the plate current. Power is calculated by multiplying the plate voltage by the plate current.

EXAMPLE: If the plate voltage (Ep) = 1,000 volts, and the plate current (I_p) = 75 MA (0.075A),
P = I x E = 0.075 x 1,000 = 75 watts.

Suppose there are two tubes in the final stage of amplification drawing 40 milliamperes each, at a plate voltage of 500 volts. The total plate current is the sum of the currents the two tubes are drawing, or 2 x 40, or 80 milliamperes. Then the input power is 500 x 0.080 = 40 watts.

How can you determine your plate voltage and your plate current? Plate voltage is measured between the plate and the cathode of the tube. Since there is negligible voltage drop across the final tank coil, the voltage may be measured at the low end of the coil if it is more convenient.

Fig.: XVII-3-1

In the diagram shown here, plate voltage may be read between A and D, A and Ground, B and D, B and Ground, C and D, or C and Ground.

CONDITIONS:

BEHAVIOR:

25. Rotate distributor in direction of firing order until the rubbing block on the contact points passes completely over the #1 distributor lobe
26. Move distributor against rotation until points start to open on the #1 lobe
27. Tighten hold-down clamp screw finger tight
28. Install distributor cap
29. Attach primary lead wire to coil
30. Recheck installation steps
31. Connect power timing light to #1 spark plug (Do not remove spark plug wire - use proper adapter)
32. Start engine and run at idle speed
33. Rotate distributor until pointer and timing marks indicate correct timing as given in specifications
34. Stop engine
35. Tighten distributor hold down screw
36. Start engine and recheck time - If timing remained the same, stop the engine

PERFORMANCE CRITERIA:

1518

Referring back to the diagram, the plate current may be measured by placing the milliammeter in series with the plate circuit or in series with the cathode circuit.

Suppose you are operating a transmitter in which you have 700 volts on the plate of the final amplifier tube. What is the maximum plate current you may be permitted to have?

First, you must remember that maximum P = 75 watts. You have E = 700 volts. All you have to do is use the formula P = I x E or I x E = P.

If I x E = P

then $I = \frac{P}{E} = \frac{75}{700}$ = 0.107 amperes or 107 milliamperes.

QUESTIONS:

1. What is the maximum power that the Novice Class operator is permitted to run?

2. Is the above <u>input</u> or <u>output</u> power?

3. If E_p = 900 volts and I_p = 60 MA, what is the input power?

4. If you have 1,200 volts on the plate of your Novice transmitter, how much current may you draw through the tube?

15220

WHO MAY OPERATE AN AMATEUR RADIO STATION

The Federal Communications Commission states that an amateur radio station may be operated only by a person holding a valid amateur operator's license. Such station may be operated by the licensee only in the manner and to the extent provided in his amateur operator's license. Persons other than the station licensee, when operating such station, may operate it "only to the extent and in the manner authorized to the licensee of the station and not exceeding the operating authority of such person's own amateur operator license." In other words, a General Class operator may operate a Novice station but only on the Novice frequencies. A Technician Class operator is not permitted to operate on the Novice frequencies for which he is not licensed. Under the old Novice licenses, when 2-meter phone operation was permitted, the Technician could operate 2-meter phone on the Novice station. Your Novice Class license, however, will not permit radiotelephone operation and, therefore, no Technician Class operator will be legally permitted to operate your station on any band.

A written record of transmissions, called a log, must be kept at each station. It must show:

1. The date and time of transmission
2. The call letters of the station called
3. The frequency band used
4. The type of emission used
5. The location of the station at the time of transmission
6. Message traffic handled (if any)
7. The signature of each licensed operator operating the equipment and the name of any person not holding a license who speaks over a radiotelephone transmitter directly or by recording, or who operates a teleprinter keyboard.

The log must be preserved for at least two years after the final entry is made in it. Also, all message traffic must be preserved for at least one year after it is handled.

When transmitting on frequencies below those in the 2-meter band, spurious radiations must be reduced in accordance with good engineering practice, and must not cause interference to near-by receivers of good engineering design not tuned to the transmitter. Voice modulation of a transmitter must not cause spurious emissions; the maximum modulation percentage is 100. Simultaneous frequency modulation and amplitude modulation is not permitted. The frequency of the signal transmitted must be as constant as the "state of the art"

15221

permits. If you feel that you might be transmitting spurious radiations or unwanted harmonics, the best way to check is to have someone about two miles away monitor your transmission and search for the suspected, unwanted emissions. Someone living very close to you cannot give you an honest report, because your transmitter could possibly be overloading his receiver. Also, very weak harmonics may be detected there that would not reach the receiver two miles away.

Even though the Novice Class transmitter must have crystal frequency control, there must be means of measurement of the frequency at the station. These means must be independent of the means used to control the transmitting frequency and must be of sufficient accuracy to ensure operation within the frequency band used. The ideal piece of equipment for this purpose is a crystal calibrator, which is used in conjunction with the receiver. This calibrator, by the way, should be checked for accuracy against the frequency of the Bureau of Standards' radio station WWV.

QUESTIONS:

1. What is the log and how long must it be kept?

2. If you are a licensed Novice Class operator, who besides yourself may operate your station?

3. What records must be kept in the log?

4. What are the FCC regulations concerning measurement of frequencies used in amateur transmission?

UNIT XVII - AMATEUR RADIO LICENSING

Lesson No. 5 — Quality of Signals

Most amateur radio transmitters are powered primarily from commercial a.c. power lines, so it is necessary that this a.c. voltage be rectified and filtered into pure d.c. before it is applied to the plates of the tubes in the transmitter. The rectifier changes the voltage from a.c. to a pulsating d.c.; from

this:

Fig.: XVII-5-1

to this:

Fig.: XVII-5-2

It is obvious that the voltage behind the rectifier is no longer going negative, but it is changing amplitude at the frequency of the a.c. if half-wave rectification was used, and at twice the frequency of the a.c. if full-wave rectification was used. This rapid change in amplitude is called ripple, and it can cause hum in any circuit where it is used on the plates of the tubes. The output from the rectifier must be smoothed by a filter network made up of inductance and capacitance. A good filter will give a B+ output like this:

Fig.: XVII-5-3

15223

15223

The output from a battery with its pure d.c. would give the same pattern on the oscilloscope.

When operating on all bands below 144 mc, the FCC requires that the plate voltages be pure d.c. This is to give a constant carrier, and one which will give a pure d.c. note.

If the output signal from a radiotelegraph transmitter is pure, then there can be no "chirp." The signal seems to chirp when there is a rapid change in the transmitter frequency upon keying, i.e. when the key is closed and opened. Keying the oscillator instead of following stages can cause chirp. Other causes may be feedback of r-f energy from the final amplifier to the oscillator, or poor regulation at the power supply, causing frequency shift.

Chirp can most often be prevented by (1) building the transmitter with a buffer amplifier stage between the oscillator and the final amplifier; (2) building the oscillator from a design which has high stability; (3) providing B+ voltages from a power supply with good regulation; (4) employing voltage regulation at the oscillator; (5) shielding the oscillator so that energy cannot feed back from later stages of amplification.

Just as overmodulation can cause spurious sidebands that are not tolerated by the FCC, key clicks can also cause spurious radiations on either side of the transmitter frequency. These radiations interfere with signals from other transmitters - possibly even signals from commercial and government stations. Key-click filters are used to prevent such spurious radiations.

QUESTIONS:

1. What is chirp?

2. Give 5 methods of preventing chirp.

3. What kind of voltage is found between the rectifier and the power supply's filter?

4. Why must the output of the rectifier-power-supply be filtered?

5. Why is a key-click filter used?

6. What is ripple?

7. The FCC is very particular about the purity of signals on what frequencies?

8. What are key clicks?

15224

UNIT XVII - AMATEUR RADIO LICENSING

Sample Test No. I

1. In the language of Amateur Radio, a cipher is

   a. a form of arithmetic
   b. a secret code
   c. the International Morse Code
   d. modulated cw

2. Radio amateurs are permitted to

   a. broadcast music
   b. make regular political speeches for their parties
   c. send, receive, and deliver commercial message traffic
   d. discuss electronic technicalities and weather

3. Persons permitted to operate a radio station licensed to a Novice are

   a. any other radio amateur
   b. qualified Army or Navy radio operators
   c. any radio amateur except the advanced extra class license holder
   d. any amateur radio operator except those holding Technician Class licenses

4. Under ordinary operating procedure (excluding short transmissions and tests) the operator must identify his station every

   a. ten minutes
   b. five minutes
   c. fifteen minutes
   d. half-hour

5. Twenty-one megacycles is which harmonic of seven megacycles?

   a. first
   b. second
   c. third
   d. fourth

6. A rectifier is used to

   a. filter ripple from d.c.
   b. change d.c. to a.c.
   c. vary amplitude of a carrier
   d. change a.c. to d.c.

7. If you are going to operate <u>portable</u> away from your base station, you must

   a. notify the FCC engineer-in-charge of the inspection district that your base station is in if you plan to operate more than 48 hours while away from the base station.

b. notify the above official if you plan to operate more than 12 hours
c. notify the FCC engineer-in-charge of the inspection district in which you intend to operate if you plan to operate more than 12 hours
d. notify the FCC engineer-in-charge of the inspection district in which you intend to operate if you plan to operate more than 48 hours.

8. What is the relationship between a kilocycle and a megacycle?

a. 1 megacycle = 100 kilocycles
b. 1 megacycle = 1×10^{-3} cycles
c. 1 megacycle = 1×10^{-6} cycles
d. 1 megacycle = 1,000 kilocycles

9. The instrument used to measure electrical potential is the

a. ammeter
b. voltmeter
c. ohmmeter
d. wattmeter

10. $I = \frac{E}{R}$ expresses

a. Krauses' Law
b. Thevenin's Theorum
c. Ohm's Law
d. Lenz's Law

11. An applicant who fails the Novice examination may take another examination

a. after 10 days from the date he failed the examination
b. after 20 days from the date he failed the examination
c. after 30 days from the date he failed the examination
d. after 60 days from the date he failed the examination

12. A modulator is used to

a. vary the amplitude, frequency, or phase of a transmitter for the purpose of transmitting information
b. change a.c. into d.c.
c. make big signals from small signals
d. pass a.c. and hold back d.c.

13. An oscillation not essential to the operation of the equipment and usually occurring on a frequency considerably removed from the operating frequency is called

a. a harmonic
b. an integral multiple
c. key clicks
d. a parasitic oscillation

15226

219 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

14. A capacitor

a. passes direct current and rejects alternating current
b. passes both a.c. and d.c.
c. effectively passes alternating current
d. rejects pulsating frequencies

15. The FCC limits antenna height because of

a. excessive power radiation
b. hazards to air navigation
c. neighborhood appearance
d. interference to marine navigation

16. You may not communicate with some countries because of

a. strained relations with those governments, war, etc.
b. differences in technical arrangements, frequencies, etc.
c. power inputs in the transmitters of their stations
d. communications laws in those countries

17. A Novice station running full power has 1200 volts on the plates of a pair of tubes in the final amplifier. How much current is being drawn by the plates of each tube?

a. 62 mA
b. 31 mA
c. 620 mA
d. 920 mA

18. Frequencies between 3700 and 3750 kc are found in the

a. 80-Meter band
b. 40-Meter band
c. 10-Meter band
d. 2-Meter band

19. If a Novice station at full power has 40 mA of I_p on the plate of the final amplifier, E_p is

a. 1875 volts
b. 300 volts
c. 3000 volts
d. 187.5 volts

20. If the signal input voltage to a transistor amplifier is 0.2 volts and the output voltage of the amplifier is 5 volts, the amplification factor is

a. 25
b. 10
c. 7
d. 1

219
15227
15227

UNIT XVII - AMATEUR RADIO LICENSING

Sample Test No. 2

Since the FCC examinations are given in the multiple-choice form, the following multiple-choice questions should give the student an idea as to how he will be questioned on those examinations.

1. A radio-frequency choke

   a. opposes currents of radio frequencies and passes d.c. currents
   b. passes currents of radio frequencies and opposes a.c. currents
   c. passes audio frequencies and opposes radio frequencies
   d. passes radio frequencies and opposes direct current

2. Amplification is

   a. the process of modulation by controlling the amplitude at the rate of the modulator's frequency
   b. the process of increasing the amplitude or power level of a signal
   c. attenuation of the signal at audio frequencies
   d. any multiple of the fundamental

3. If a tube does not heat up when the filament voltage is turned on, it is caused by

   a. the plate voltage being off
   b. the center tap of the high-voltage secondary being disconnected
   c. probably the filament pins of the tube are not making contact at the tube socket
   d. the filament voltage having ripple

4. The plate voltage of the final amplifier tube in a transmitter may be measured between

   a. the cathode and B+ end of the RF choke in the plate circuit
   b. the plate and the B+ end of the RF choke in the plate circuit
   c. the grid and the B+ end of the RF choke in the plate circuit
   d. the cathode and the screen grid

5. The Novice frequencies in the 40-meter band are those between

   a. 3700 and 3750 kc
   b. 7.150 and 7.200 mc
   c. 21.1 and 21.25 mc
   d. 7.15 and 7.2 kc

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: II. IGNITION SYSTEM - DISTRIBUTOR

PERFORMANCE OBJECTIVE NO.: 2 TITLE: Remove, Disassemble, Reassemble, Replace, and Adjust Distributor

CONDITIONS:

BEHAVIOR:

37. Remove timing light
38. Connect vacuum control line
39. Recheck all wires and connections
40. Replace air breather assembly
41. If distributor functions satisfactorily, clean and replace tools and materials
42. Remove fender covers and store in proper place
43. Close hood
44. Return automobile to proper parking area
45. Remove seat cover and store in proper place
46. Clean work station for next project

PERFORMANCE CRITERIA:

To be able to satisfactorily remove, disassemble, reassemble, replace, and adjust distributor in 2 hours and 30 minutes.

Learning time: 6½ hours

1519

14. A filter choke is used for

a. passing RF and rejecting AF
b. smoothing RF signals
c. smoothing the d.c. output of a rectifier
d. none of the preceding

15. Ohm's law states that

a. Power equals voltage multiplied by current.
b. For finding current, resistance is inversely proportional to voltage.
c. For finding current, resistance is directly proportional to voltage.
d. For finding resistance, the current is directly proportional to voltage.

16. To make an amateur radio station safe, one should

a. make sure all power supplies have bleeder resistors
b. install interlock switches on lids and panel openings of all high-voltage equipment
c. have the cabinets of all components in the station connected to a good common ground
d. use all of the above precautions

17. There are two tubes in the final amplifier of a transmitter. E_p = 500 V and each tube is drawing 0.05A. Input power is

a. 25 watts b. 250 watts c. 50 watts d. 500 watts

18. A frequency multiplier is

a. a device that delivers output power at integral multiples of the frequency
b. a device that delivers frequencies at integrals of the applied frequency
c. a device that amplifies the oscillator signal at integral multiples
d. a device to be avoided because it can put your signal outside the bands of frequencies permitted by the FCC

19. Wavelength (in meters) may be found by

a. dividing 300,000,000 by the frequency (in Hz)
b. dividing 186,000 by the frequency (in c.p.s.)
c. multiplying the frequency (in c.p.s.) by 300,000,000
d. multiplying the frequency (in Hz) by 186,000

20. One method of correcting harmonic radiation is to

a. lower the plate voltage
b. use lower-C interstage circuits
c. use higher-C interstage circuits
d. increase grid drive

21. in the diagram shown below, the block designated by the letter B is

a. the modulator
b. the final tank circuit
c. the oscillator
d. the buffer amplifier

22. Also, in the diagram shown above, the block designated by the letter A is

a. the power supply
b. the oscillator
c. the final amplifier
d. the buffer amplifier

23. In the same diagram, the block designated by C is

a. the modulator
b. the oscillator
c. the final amplifier
d. the buffer amplifier

15231

24. A key-click filter is used in a transmitter design for

a. safety purposes
b. limiting spurious emissions
c. protection to the tubes
d. the elimination of sidebands in the radiotelephone transmitter

25. In the diagram at the right, R_T is equal to

a. 76Ω
b. 2Ω
c. 14Ω
d. 28Ω

26. In the above diagram, I_{R_4} is equal to

a. 2 A b. 3 A c. 5 A d. 7.15 A

27. 1 μμF is equal to

a. 1×10^{-12} farads
b. 1×10^{-6} μF
c. 0.000000000001 farads
d. all of the above

28. The instrument which is used to measure electrical energy is

a. the voltmeter
b. the wattmeter
c. the watt-hour meter
d. the galvanometer

15232

WILLIAM THOMSON, LORD KELVIN (1824–1907).

A British physicist and electrical engineer; born in Belfast, Ireland; for more than fifty years professor of physics in Glasgow University, Scotland; invented the mirror galvanometer used in cable signaling; developed an improved form of mariners' compass. His work in thermodynamics is of the greatest value. He was one of the first to appreciate the principle of CONSERVATION OF ENERGY.

15233

UNIT XVIII - ALTERNATING CURRENT

Lesson No. I — What is AC?

There are basically two different kinds of electric currents - DC and AC. You have been studying d.c. and, of course, understand that it flows in one direction. Alternating current switches direction constantly, the number of times per second depending upon the frequency. If it is a 60-cycle current (the frequency of house current) the direction changes to the opposite and then back 60 times per second. In a 60-cycle current, therefore, there are actually 120 direction changes in a second.

If you turn on an electric light in your home, the instant you turn it on the current may be flowing in the direction of the arrow shown in the upper illustration.

Fig.: XVIII-1-1

In a small fraction of a second, the current will be flowing in the opposite direction. It will change directions 120 times each second, making 60 complete cycles each second.

Fig.: XVIII-1-2

15234

TO COMPLETE THE CYCLE, THE CURRENT MUST RETURN TO THE ORIGINAL DIRECTION. THEREFORE, THERE ARE TWO CHANGES IN EACH CYCLE - FROM ONE DIRECTION TO THE OPPOSITE, AND THEN BACK AGAIN.

Resistance is the only impeding force that d.c. (direct current) meets. In a-c (alternating current) circuits, though, there are other forces which tend to hold back or lessen the current-flow. These forces are called reactances, and when all the reactances, along with the resistance, are combined, we call the composite force impedance.

There are two kinds of reactance. One is called capacitive reactance (X_C). Capacitive reactance is the resistance to a current due to a capacitor or the capacitance effect of the wires themselves. The other is inductive reactance (X_L). Inductive reactance is the resistance to a-c current due to inductance. This inductance may be caused by the wires or by a coil designed for that purpose.

Direct current from the battery in the circuit below will not flow through the capacitor.

Fig.: XVIII-1-3

15234
15235

Alternating current, however, will effectively flow through a capacitor.

Fig.: XVIII-1-4

The capacitor does not allow all of the a.c. through. It has an impeding force — a holding-back force — which varies in strength according to the value of the capacitance and the frequency of the a.c. This reactance is called capacitive reactance and is designated "X_C."

Let's study the diagram shown below. If there is no d.c. resistance in the coil, it will offer no opposition to the flow of d.c. coming from the battery.

Fig.: XVIII-1-5

If, however, a source of a.c. replaces the battery, this a.c. will find an impeding force in the coil which will tend to hold it back.

Fig.: XVIII-1-6

The impeding force which holds back the flow of a.c. is known as inductive reactance (X_L). The strength of this reactance will be governed by the inductance in the coil <u>and</u> the frequency of the alternating current.

In a-c circuits, we may be faced with these opposing forces - capacitive reactance (X_C), inductive reactance (X_L), and also resistance (R). These opposing forces combine to make up a resistance force known as <u>impedance</u> (Z).

ASSIGNMENT:

1. What is the difference between a.c. and d.c.?

2. What is the frequency of ordinary house current?

3. Does an automobile battery furnish a.c. or d.c.?

4. Will a.c. pass through a capacitor?

5. Will a coil having no resistance oppose the flow of alternating current?

6. What are the letters or symbols representing impedance, capacitive reactance, and inductive reactance?

7. What is the effect of inductive reactance on the flow of direct current?

15237

UNIT XVIII - ALTERNATING CURRENT

Lesson No. 2 Generation of AC

You remember that if a conductor moves between the north and south poles of a magnet, cutting the lines of magnetic flux, a current is made to flow in that conductor if it is in the form of a loop; and the direction of this current-flow is determined by the direction the conductor is moving through the magnetic lines. You should also remember that the number of lines being cut in a certain time (a unit of time) determines the amount of e.m.f. generated. The stronger the magnet (the more lines of flux), the greater will be the voltage.

Look at Figure 1 below. It shows in a simplified form how an alternating current is generated by the movement of a coil of wire. The positions (A) through (E) show the position of a loop of wire (which is going to carry off the current produced) in relation to the poles of a magnet. The curved line below is a graph of the e.m.f. produced by one complete rotation of the loop. One complete rotation is 360°; a half rotation is 180°.

Basic alternating-current generator.

Fig.: XVIII-2-1

If you will look at position A in the figure, you will be able to tell that the conducting loop is cutting no lines at that position. The movement of the conductors is practically parallel with the lines. When the conductors are at the position B or D, they are cutting more lines in a unit of time than they would be cutting at any other position.

Now, bearing in mind that the conductors are rotating at an even speed, think how many lines they would be cutting when at a position halfway between A and B. Concentrate on this until you fully understand why the current or voltage would be higher at B than at C or E. Make sure that you understand this. Your shop instructor will explain it to you more than once, if necessary, because he knows that this is a basic idea that you must understand before you can proceed to an understanding of alternating current.

You understand how the current increases and decreases, or how the voltage rises and falls according to the position of the conductors in the magnetic field of an a-c generator. The next thing that you need to understand is how the current alternates its direction — that is, goes one way and then back the other way. Let's look at the heavy-lined part of the conductor in Figure B. The arrow indicates that this portion of the loop is moving down through the lines of flux. Now, if you remember your lessons in MAGNETISM you can visualize the conductor wrapping the lines around it in this manner.

Fig.: XVLII-2-2

You will remember too that if the direction of the magnetic field around a conductor is in a counterclockwise direction as shown above, the current will be going away from you and will be indicated in this manner.

Fig.: XVIII-2-3

When the conductors come back up through the field, as shown in D, the current will be reversed, as shown. Now, if you will, in your imagination follow the heavy end of that coil as it rotates. You can understand how - looking into the end of the conductor - the current will go first in one direction and then in the other during one full rotation. This is one cycle - to an opposite condition and then back to the original.

15239

If the direction is changed, but does not come back to the original direction, that is an alternation. There are two alternations in each cycle in alternating current. There are 120 alternations per second in 60-cycle current.

Notice the form of the curve in Figure XVIII-2-1. It is called a sine curve or sine wave (from the "sine" of an angle, in trigonometry). You will come across this form of curve many, many times in your study of electricity. In this case it shows how the e.m.f. varies as the coil turns through a right angle (90°), a straight angle (180°) and back to the original position (360°).

ASSIGNMENT:

1. Draw the symbol used for an a.c. supply of e.m.f. Tell what the curve in it means.

2. The conductor shown in the diagrams below represents a single turn of an armature winding.

Observe the position of the armature winding as it is in the magnetic field, and match armature position to the instantaneous value on the sine wave (the correct number on the curve).

A ___ B ___ C ___ D ___

15240

UNIT XVIII - ALTERNATING CURRENT

Lesson No. 3 Reactance and Impedance

In the first lesson in this unit you learned that there are "holding back" forces in a-c circuits other than just resistance. You learned that a coil can resist a.c., yet it will permit d.c. to pass. You also learned that d.c. will not pass through a capacitor while an alternating current seems to pass through it. These forces are called reactances. Reactance is indicated by the letter "X". The subscripts "C" and "L" indicate whether the reactance is capacitive or inductive. X_C stands for that force in a capacitor which tends to hold back some of the flow of a.c. X_L stands for that force in an inductor which tends to hold back some of the flow of a.c. The relationship of those forces to one another is one of the interesting aspects in the study of alternating current.

You may have a circuit like this

Fig.: XVIII-3-1

and you know that the resistor will lessen the value of current. You know, too, that when the capacitor is added, the current will be cut down to an even smaller value. The interesting fact, now, is that it is possible to add another component which one would at first think would cut the current even more, and this component (an inductor) can increase the current instead of decreasing it.

IT IS IMPORTANT THAT YOU DO NOT GET THE IDEA THAT THIS IS ALWAYS THE CASE. IT IS ONLY WHEN THE INDUCTOR CAN REDUCE THE OVERALL VALUE OF REACTANCE THAT MORE CURRENT WILL FLOW IN THE CIRCUIT.

If the capacitive reactance is 10 ohms and you place an

15241

inductor with 13 ohms inductive reactance in series with the circuit like this,

Fig.: XVIII-3-2

the two reactances "buck" each other and leave the circuit with an overall reactance of 3 ohms. So far as the passage of total current goes, the circuit will "look like this" to the current.

Fig.: XVIII-3-3

This is because inductive reactance and capacitive reactance are one half-cycle (180°) out of phase with each other. Inductive reactance and capacitive reactance in series affect one another like this:

(a) A capacitive reactance of 2 ohms in series with an inductive reactance of 9 ohms results in an inductive reactance of 7 ohms.

(b) A capacitive reactance of 9 ohms in series with an inductive reactance of 5 ohms results in a capacitive reactance of 4 ohms.

(c) A capacitive reactance of 4 ohms in series with an inductive reactance of 4 ohms cancel each other and leave the circuit with no reactance at all. It is as if neither were in the circuit.

Opposing forces (180° out of phase) pull against one another like this

Fig.: XVIII-3-4

Reactance is also 90° out of phase with resistance. They oppose one another like this

Fig.: XVIII-3-5

If a circuit has 4 ohms of resistance and 3 ohms of inductive reactance, these quantities may be shown graphically like this

Fig.: XVIII-3-6

When the reactance is placed at the end of the line representing resistance in such a way as to make a right angle (90°), a right triangle may be formed by closing it in with the hypotenuse. The value of the hypotenuse will be the value of the impedance (Z). All of the forces which tend to hold back alternating current go to make up impedance in this manner.

Just in case some of you have forgotten how to find the value of the hypotenuse of a right triangle, let's go through one. Suppose a circuit has 4 ohms of inductive reactance and has 3 ohms of resistance. What is the value of the impedance?

$$Z = \sqrt{R^2 + X^2} = \sqrt{3^2 + 4^2} = \sqrt{9 + 16} = \sqrt{25} = 5 \text{ ohms}$$

If there is more than one inductive reactance (X_L) or capacitive reactance (X_C), the like reactances can be added before calculating the impedance. That is, X_L can first be added to any other X_L's or X_C can first be added to any other X_C's.

SP 15243

ASSIGNMENT:

1. Find the value of the hypotenuse in each of the following triangles.

2. If a circuit has a capacitor which produces 15 ohms of capacitive reactance in series with 8 ohms of inductive reactance, what is the overall reactance? Is it capacitive or inductive?

3. Suppose the circuit in No.2 has a 10-ohm resistor added in series with it, what will be the value of the impedance of the circuit?

UNIT XVIII - ALTERNATING CURRENT

Lesson No. 4 AC Power Transmission

The fact that there are some radiation losses from an a.c. line, along with difficulties encountered from capacitive and inductive reactances, could make one wonder why d.c. isn't used for transmitting electric power instead of a.c.

If it were not for the fact that it is so easy to step up a.c. to high-voltage levels by means of transformers and then back down again, we probably would have d.c. coming into our homes today. Thomas A. Edison was very much against a.c. power transmission when Nikola Tesla influenced the construction of the original power plant at Niagara Falls.

There was much indecision until Lord Kelvin was consulted. This great British scientist agreed with Tesla and George Westinghouse, and the plant was designed to produce alternating current for public consumption.

If you will examine a 5-ampere fuse and a 1-ampere fuse, you will see that the conductors in the 5-ampere fuse are considerably larger than in the 1-ampere fuse. Bear in mind that it takes a large conductor to carry high currents. You know that the formula for power is $P = I \times E$, that is

Power (in watts) = I (in amperes) X E (in volts).

Perhaps you can imagine how large the long-distance conductor would have to be in order to supply the power needed in even a small village if the line voltage were 110 volts instead of, say, 44,000 volts.

Remember, now, it is not commercially practical to alter d.c. in such a way as to make transformer action practical. So d.c. would have to be transmitted to the village at the voltage level at which it is to be used.*

---

*During the writing of this book, a power company in California was erecting a system for the transmission of high voltage d.c. with modern methods of converting to a.c. at the distribution points. They point out that in the long run, this cheaper due to the savings on insulators. As you know, a.c. needs insulation at its peak voltage, whereas d.c. needs insulation for only 70.7% of that value. The effective value of a.c. is only 0.707% times its peak value.

15245

EXAMPLE: Suppose there are 500 homes in a village, and each is burning ten 100-watt light bulbs and consuming another 1,000 watts in household appliances. This makes 2,000 watts of power being used in each house. If you multiply this by 500, you will see that the village is consuming 1,000,000 watts. Now, how many amperes of current from a 110-volt source would it take to produce a million watts?

If $P = I \times E$, then $I = \frac{P}{E}$

$$I = \frac{P}{E} = \frac{1,000,000}{110} = 9,100 \text{ amperes}$$

Now if the line voltage of the transmission line going into the village is 44,000 volts, how much current will the line have to carry?

$$I = \frac{P}{E} = \frac{1,000,000}{44,000} = 22.7 \text{ A}$$

There is a lot of difference between 22.7 amperes of current and 9,100 amperes of current! Again, look at the 5-ampere fuse and the 1-ampere fuse and again think how large the power transmission lines would have to be if they carried over 9,000 amperes of current.

Remember, in transmitting power - the higher the voltage, the lower the amperage may be to deliver the power.

ASSIGNMENT:

1. A transmission line carries power at 132,000 volts. How much current must it carry if it is supplying a community which is using 2.5 million watts of electric power?

2. A line carrying 15 amperes is supplying 3,300 watts of electric power. What is the voltage of this line?

3. Why is a.c. used instead of d.c. in the transmission of electric power?

UNIT XVIII - ALTERNATING CURRENT

Lesson No. 5 — Wavelength

"Wavelength" is a term you have probably heard for a long time. Perhaps you have formed ideas as to what wavelength really is. Let's see how close you have been to understanding wavelength.

First, let's remember that electricity and light travel at a speed of 300,000,000 meters per second (186,000 miles per second). Try to visualize a radio transmitter operating at a frequency of 30 megacycles - thirty million cycles per second.

In one second the oscillator in the transmitter has changed the polarity of the voltage to the antenna from + to - and back to + 30,000,000 times! This being a radio frequency, the signals, when sent to a properly constructed antenna, will leave the antenna and radiate many miles through the air.

If there are 30 million oscillations per second between the transmitter and the receiver, then there must be a certain measurable distance between those oscillations.

If there are 30,000,000 in a distance of 300,000,000 meters, the distance between two peaks of the wave must be

$$\frac{300,\cancel{000},\cancel{000}}{30,\cancel{000},\cancel{000}} = 10 \text{ meters}$$

15247

The distance between two adjacent (next-to-each-other) peaks is called the wavelength. The symbol for wavelength is the Greek letter lambda (λ).

The formula for finding wavelength is

$$\lambda = \frac{300,000,000}{f}$$

where f = frequency in cycles per second.

EXAMPLE: What is the wavelength if the frequency is 30 megacycles?

$$\lambda = \frac{300,000,000}{f} = \frac{300,000,000}{30,000,000} = 10 \text{ meters}$$

Of course, the answer is in <u>meters</u> since the figure 300,000,000 is the distance given in meters per second.

Just in case you should ever forget the formula, you can always refresh your mind and check it by remembering that 30 megacycles is in the 10-meter amateur radio band.

If you are interested in amateur communications, you should also know that 50 megacycles is in the 6-meter band. Let's see if the formula proves that.

$$\lambda = \frac{300,000,000}{50,000,000} = 6 \text{ meters}$$

It is possible that sometimes you may know a wavelength and need to know the frequency. From algebra, you know that the formula is still true if you exchange λ with f.

$$\text{from} \quad \lambda = \frac{300,000,000}{f} \quad \text{to} \quad f = \frac{300,000,000}{\lambda}$$

Let's go back to the 6-meter example and see if 50 megacycles falls into the 6-meter band.

$$f = \frac{300,000,000}{\lambda} = \frac{300,000,000}{6} = 50,000,000 \text{ cycles per second}$$

While talking about frequency and wavelength, perhaps now would be a good time to know which are the VHF (very high frequency) bands and which are the UHF (ultra high frequency) bands.

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV ELECTRICAL SYSTEM

MILESTONE: III IGNITION SYSTEM - SECONDARY WIRING

PERFORMANCE OBJECTIVE NO: 3 TITLE: Remove and Replace Secondary Wiring

CONDITIONS: Student will learn the related information listed below

LEARN	REFERENCE	SOURCE
1. Determining firing sequences	1.	1. Shop Instructor
2. Secondary wiring	2. Automotive Electrical Equipment, by Crouse, pp. 413 and 414 Automotive Electrical Equipment Workbook, by Crouse, Job 39	2. Related Information Class
3. Coils	3. Automotive Electrical Equipment, by Crouse, pp. 405 through 413 Automotive Electrical Equipment Workbook, by Crouse, Job 40	3. Related Information Class
4. "Installing Spark Plug Wire Terminals"	4. Continuous film loop # 8377	4. Resouce Materials Center

The FCC (Federal Communications Commission) has classified them as follows:

Frequency	Classification	Abbreviation
10 to 30 kc.	Very low frequencies	v.l.f.
30 to 300 kc.	Low frequencies	l.f.
300 to 3000 kc.	Medium frequencies	m.f.
3 to 30 Mc.	High frequencies	h.f.
30 to 300 Mc.	Very high frequencies	v.h.f.
300 to 3000 Mc.	Ultrahigh frequencies	u.h.f.
3000 to 30,000 Mc.	Superhigh frequencies	s.h.f.

What are microwaves? "Micro," as you know, is used for something very, very small. The term microwave is rather loosely used. It is applied to those wavelengths that have frequencies above 1,000 megacycles. So, actually, the upper half of the UHF range could be called microwaves. The actual UHF television frequencies do not quite fall into the microwave classification, however, because the top UHF television frequency is 890 megacycles.

ASSIGNMENT:

1. If a transmitter is operating at a frequency of 1500 kc., what is the wavelength of its signal?

2. What is the frequency of a 40-meter signal?

3. What are microwaves?

4. If a transmitter is operating at 40 Mc., is it in the medium, high, veryhigh or ultrahigh frequencies?

5. What is wavelength?

15249

UNIT XIX - EFFECTS OF CAPACITANCE AND INDUCTANCE

Lesson No. 1 — Capacitors

To understand a capacitor, it is best to look at one in its simplest form - nothing but two metal plates separated by a thin layer of material called a dielectric.

Fig.: XIX-1-1 Simple capacitor.

The dielectric can be any of many types of insulating material, including air. Whatever the composition of the dielectric, it must prevent electrons from moving through the capacitor at the rated voltage. The dielectric determines the rated voltage of a capacitor. As the capacitor is charged, the two opposite charges on the plates distort the electron orbits of the dielectric. When the charge is great enough, it will remove one or more electrons from atoms of the dielectric and cause a weak spot, if not a hole. The capacitor then leaks - and must be replaced. This is why we must never use a capacitor above its rated voltage.

15250

Fig.: XIX-1-2

How does the capacitor work? When the capacitor is connected in a circuit, as illustrated in Figure 3, the electrons from the negative side of the power supply begin to move to the negative plate.

Fig.: XIX-1-3

This movement is almost immediately retarded by the mutual repulsion of the electrons on the plate. The charging continues at an ever-decreasing rate until the applied e.m.f. can no longer move electrons onto the plate. The capacitor is then as charged as it can get at that voltage. An increased e.m.f. (voltage) could cause a greater charge.

While the negative side is gaining electrons, the positive side is losing electrons to the positive side of the power supply. This process is much the same as that on the negative plate. The major difference is that on the positive plate the loss of electrons is retarded by the increasing positive charge due to more and more unbalanced protons (positive charges), rather than more and more unbalanced electrons.

You could now remove the capacitor from the circuit and you would remove the charge with it. The capacitor could be discharged, causing a current to flow until the capacitor was fully discharged.

How quickly can a capacitor charge? This depends upon the size of the capacitor and the circuit, but most capacitors charge in extremely small fractions of a second. The larger the capacitor, the longer it takes to charge in any given circuit.

The charging of a capacitor involves a transfer of current. At the instant a capacitor is connected into the circuit, it has practically no resistance. At that instant we could apply Ohm's law

15250

15251

to the rest of the circuit and determine the current flow. As soon as the electrons begin to charge the capacitor, however, its resistance increases. This resistance increases sharply as the capacitor first charges, and the increase tapers off toward the end of the charge period. The rate of resistance increase is termed exponential (logarithmic). Thus, whenever we have a capacitor in a circuit, it will tend to make the current follow an exponential waveform, with a constant decrease until the current is zero when the capacitor is fully charged. Figure 4 is a graph showing how the charging affects various important characteristics.

Rise of Voltage in a Practical Capacitor
Fig.: XIX-1-4

When a capacitor is discharged, the process is just the reverse, as shown in Figure 5.

Fig.: XIX-1-5

The charge-discharge-rate characteristic is very important. In many applications capacitors are used to make time-constant circuits. You can see why it is important that we know the time constant. It is also important to remember that increased circuit resistance can increase the time constant. Increased circuit resistance, of course, decreases the applied e.m.f. across the capacitor. Without further discussion at this point, also remember that a.c. is a constantly changing applied e.m.f.

15252

ASSIGNMENT:

1. What does a capacitor do?

2. What is a dielectric?

3. What happens to the atoms in the dielectric when a capacitor takes on a charge?

4. Does a capacitor charge at a linear rate?

5. Explain the difference between a linear rate of change and an exponential rate of change.

15253

15253

UNIT XIX - EFFECTS OF CAPACITANCE AND INDUCTANCE

Lesson No. 2 — Units and Behavior

Like almost everything else, there is a need for some way of measuring capacitance. Before learning how capacitance is measured, though, let us find out what a coulomb is. A coulomb is a unit of charge. Actually, an absolute coulomb is defined as "the amount of electrical charge which crosses a surface in one second if a steady current of one absolute ampere is flowing across the surface." The unit of capacitance is called the farad in honor of Michael Faraday. It is the amount of capacitance which permits a capacitor to take on a charge of one coulomb when one volt is applied.

The farad is a very large unit - much larger than we normally encounter. The values we work with are much smaller. They are usually on the order of millionths of farads, or millionths of millionths. You have heard the term microfarad. It is 1/1,000,000 or 1×10^{-6} farad. Perhaps you have also heard of the micro-microfarad. It is one millionth of one millionth or 1×10^{-12} farad, often written as 1 μμf and sometimes called the picofarad.

1 farad = 10^6 microfarads
1 farad = 10^{12} micro-microfarads
1 microfarad = 10^{-6} farad
1 micro-microfarad = 10^{-12} farad

Fig.: XIX-2-1

Study this table and learn the different ways of noting capacitance values and their relationships to each other.

The values of ceramic, mica, and paper capacitors are often shown in color-code. The colors represent the same numbers that they do on resistors. There are several methods of placing these colors on capacitors, however. Some are given in Figure 2.

15254

CAPACITANCE

B = BLACK MEANS MICA MIL ONLY

S = SILVER MEANS PAPER

1 = FIRST DIGIT

2 = SECOND DIGIT

3 = THIRD DIGIT

4 = MULTIPLIER

5 = TOLERANCE

6 = CHARACTERISTIC

VOLTAGE RATING IS INDICATED BY DIMENSION RATHER THAN COLOR CODE

Fig.: XIX-2-2

It is said that capacitors "pass" a.c. This is actually what happens:

The capacitor charges as shown here when a voltage is applied.

Fig.: XIX-2-3

When the applied voltage reverses polarity, the capacitor discharges the charge just taken on and becomes charged with reversed polarity.

Fig.: XIX-2-4

At the beginning of each alternation, the capacitor charges, and there is current in the circuit during this time. When the input polarity reverses, the capacitor will discharge, causing current to flow in the opposite direction. This goes on and on - back and forth - but the current never really goes through the capacitor. Even though the current does not go through it, the effect is the same, since there is a flow of alternating current in the circuit. So you can say that a.c. effectively passes through a capacitor.

Let's review:

1. A microfarad is one one-millionth of a farad. The Greek letter mu (μ), meaning in electronics one one-millionth or 1×10^{-6} is often used like this — 1 μf. 1 μf = 1 microfarad.

2. One micro-microfarad is one millionth of a millionth of a farad. It may also be noted as 1 μμf or 1×10^{-12} farads. A micro-microfarad is also called a picofarad.

15256

Color	1st Digit	2nd Digit	Multiplier	Tolerance (Percent)
Black	0	0	1	
Brown	1	1	10

Gold			.1	5
Silver			.01	10
No Color				20

Resistor Color - Code Table

ASSIGNMENT:

1. Referring to the capacitance color chart, what would be the value of a mica-type capacitor if the colors are WHITE RED GREEN ORANGE BROWN SILVER?

   (HINT: Do not worry about characteristics. They aren't used enough for you to consider them at this time. They are used in military electronics, generally, to designate test methods and sometimes temperature coefficients.)

2. Referring to the capacitance color chart, what would be the value of a capacitor (also mica) if the colors are BLACK YELLOW GREEN BLACK GOLD BROWN?

3. How many microfarads are 35,000 micro-microfarads?

4. How many μμf are 100 μf?

5. What is a picofarad?

15257

UNIT XIX - EFFECTS OF CAPACITANCE AND INDUCTANCE

Lesson No. 3 — Capacitive Reactance

Capacitors, as you know, effectively pass a.c., but there can be a "holding back" force which will lessen the flow of a.c. This "holding back" force in a capacitor is called capacitive reactance. It is noted as (X_C). The letter "X" stands for reactance. The subscript "C" stands for capacitance. So X_C stands for reactance found in capacitance.

The higher the frequency of the applied voltage (that is, the faster it changes from positive to negative and then back), the easier it is for a.c. to effectively pass through the capacitor. Also, the higher the value of capacitance, the easier it will be for the alternating current to pass.

We must remember now that high currents can pass only when there is small reactance.

Since reactance is a "holding back" force, a resistance, it is measured in ohms.

The formula for finding capacitive reactance is

$$X_C = \frac{1}{2\pi f C}$$

π = 3.14, and C = number of cycles

EXAMPLE: Suppose there is a 1 μf capacitor in series with a 60-cycle a.c. circuit. What is the value of the capacitive reactance?

$$X_C = \frac{1}{2\pi f C} = \frac{1}{6.28 \times 60 \times 1 \times 10^{-6}} \overset{*}{=} \frac{1 \times 10^{6}}{377}$$

$$= 377\overline{)1{,}000{,}000}^{\,2{,}653} = 2{,}653 \text{ ohms}$$

* Remember, when you carry powers of ten across the fraction bar, the sign of the exponent changes. Thus, when the 10^{-6} was carried up to the top, the numerator became 1×10^{6} or 1,000,000.

Let's assume that the frequency is double that in the problem we just worked. How would doubling the frequency affect the capacitive reactance?

15258

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: III. IGNITION SYSTEM - SECONDARY WIRING

PERFORMANCE OBJECTIVE NO.: 3 TITLE: Remove, Test, and Replace Secondary Wiring

CONDITIONS:

This assignment will be performed on a complete automobile.

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective cover on seat of automobile
2. Move automobile into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper manuals and turn to appropiate chapter
6. Select proper tools and materials
7. Disconnect battery ground cable
8. Remove air breather assembly
9. Mark #1 spark plug wire terminal in distributor cap
10. Unsnap the two retainer clips and lift distributor cap free of distributor
11. Remove secondary coil wire from center of coil
12. Remove secondary wire from spark plugs
13. Remove clamps holding secondary wires to engine
14. Lift distributor cap and secondary wiring assembly from engine

PERFORMANCE CRITERIA:

$$X_C = \frac{1}{2\pi f C} = \frac{1}{6.28 \times 120 \times 1 \times 10^{-6}} = \frac{1{,}000{,}000}{753}$$

$$= 753\overline{)1{,}000{,}000}^{\,1{,}328} = 1{,}328 \text{ ohms}$$

NOTE: When we doubled the frequency, we halved the capacitive reactance.

Since X_C becomes less when either the frequency or the capacitance increases, the capacitive reactance is said to be <u>inversely proportional</u> to the value of capacitance or of frequency.

ASSIGNMENT:

Solve for the value of capacitive reactance in each of the following circuits.

A

B

C

D

15259

Joseph Henry (1797-1878)

Joseph Henry was born in Albany, N. Y. in 1797. (This was not too long after our nation became independent). He attended a country school, and later attended the Albany Academy. Being very interested in electricity, he spent most of his time in the study of its action. His experiments and discoveries formed the basis for the development of the telegraph, telephone, radio, and the electric motor. He was the discoverer of self-induction in electrical conductors. He later became professor of natural philosophy at Princeton University, and in 1842 Congress appointed him to be the first secretary of the Smithsonian Institution. He founded the U. S. Weather Bureau - one of the many scientific advancements he inaugurated for our country. He was considered the leading American physicist of his time. The unit of inductance is named in his honor.

15260

UNIT XIX - EFFECTS OF CAPACITANCE AND INDUCTANCE

Lesson No. 4 Inductance

An inductor is nothing but a coil of wire. These coils come in many sizes and shapes, as you can see from the pictures on this page.

What does an inductor do? It tends to oppose any change in the current going through it. At any instant that the current flowing in an inductor is increasing in value, the inductance will be tending to hold back that current. If at any instant the current happens to be decreasing in value, the inductance will tend to increase the current. This is in accordance with Lenz's law. Lenz's law states that an induced magnetic field will be in such direction as to oppose the inducing field.

If a battery is connected to a lamp through long straight wires, the lamp will immediately light. There will be no lag in the current. If an inductor is placed in series with the lamp - of if the line is wound in enough turns - the lamp will take some time in reaching its full brilliancy. This is due to back e.m.f. or the effect of induction. Back e.m.f. is caused by the fact that each turn in a coil induces a voltage in its neighboring turns, which will cause a current in direct opposition to that coming from the source voltage. This is called <u>self-induction</u>.

15261

Fig.: XIX-4-1

Joseph Henry, the American physicist, and the English scientist Michael Faraday were both working with coils at the same time. Henry demonstrated back e.m.f. from self-induction. We can demonstrate it in the following manner.

Fig.: XIX-4-2

When the switch is closed, the light flashes brightly for just an instant and then grows dim. When the switch is opened, the lamp goes out, but before going out it again gives a bright flash.

When the switch was closed, back e.m.f. prevented the current from reaching a maximum through the coil; but when the back e.m.f. ceased, the coil then relieved the lamp of some of its current. This is why the lamp grew dim. When the switch was opened, cutting off the current from the battery, the collapsing field in the inductor induced an e.m.f., and the current from this self-induced e.m.f. discharged through the lamp, bringing it again to maximum brilliancy.

Faraday was early in reporting his findings. He made some of them known to the scientific world through his report to the Royal Society in 1831. One of his most outstanding experiments was the one where he wrapped two closely-wound coils around a wooden core, connecting a battery and a galvanometer in the following manner.

Fig.: XIX-4-3

15262

When he closed the switch, the needle would indicate a current-flow in one direction. When he opened the switch, the needle would show a momentary flow of current in the opposite direction. Once the switch was closed, and after the galvanometer had indicated a flow of current for just an instant, no more current was indicated in the secondary coil.

This proved to Faraday that induction occurs only during the time that a current is changing in value. The galvanometer indicated current only when the current was rising in the primary winding. All during the rest of the time that the switch was closed, current was flowing in the primary, but none was flowing in the secondary. When the switch was opened and the current started falling in the primary, this change in value in the primary induced current into the secondary. Faraday had not only proven that induction occurs only during a change in amplitude of a current, but here he had demonstrated mutual inductance. Mutual inductance occurs when the expanding and collapsing field of one coil is close enough to an entirely separate coil to induce electrical energy into that coil.

When Faraday reported this to the Royal Society, he probably did not know that this would lead not only to big factories making transformers (which this really was), but also to the transmission of electromagnetic waves through the air, making possible that which we call radio.

ASSIGNMENT:

1. Give as many reasons as you can as to why inductors are manufactured in so many shapes and sizes.

2. Who was Michael Faraday?

3. Who was Joseph Henry?

4. Explain why the lamp in Henry's experiment first lit brightly and then grew dimmer.

5. Why did it not immediately go out when the switch was opened? Why did it get brighter for an instant first?

6. What is mutual inductance?

5263

UNIT XIX - EFFECTS OF CAPACITANCE AND INDUCTANCE

Lesson No. 5 R-L Time Constants

The current flowing through a coil does not immediately reach full value when a voltage is applied. Counter-e.m.f. fights the incoming current, but due to the fact that counter-e.m.f. (c.e.m.f.) exists only during the rise or fall of the incoming current, it always loses in the end, and the applied current will reach full value.

There is a formula for finding the time it takes an applied current to rise.

$$t = \frac{L}{R}$$

t = the time (in seconds) it takes the current to reach 63.2% of its full value. This time is called the <u>time constant</u>.

L = the inductance (in henrys)

R = the resistance (in ohms)

Suppose we have a circuit like this.

Fig.: XIX-5-1

You know immediately (from your knowledge of Ohm's Law) that the current in this circuit will be 10 amperes. It will take some time for it to reach 10 amperes, however, because of the effect of inductance. Let's see how long it will take for the current to rise to 63.2% of 10 amperes.

$$t = \frac{L}{R} = \frac{50}{25} = 2 \text{ seconds}$$

15264

We know that in 2 seconds the current is 6.32 amperes (6.32 is 63.2% of 10). The current must still rise to get to 10 amperes.

In another time constant, the current will increase 63.2% of the remainder, or 63.2% of (10 - 6.32) - or 63.2% of 3.68.

63.2% of 3.68 = 2.33, so at the end of 4 seconds (2 time constants) the current is 6.32 A + 2.33 A, or 8.65 amperes.

There is now a difference between 8.65A and the full 10A. In another time constant, the current will be that at 4 seconds plus 63.2% of the difference between 8.65 and 10.

10 - 8.65 = 1.35

63.2% of 1.35 = 0.85

8.65 + 0.85 = 9.5

The current has risen to 9.5 amperes at the end of 3 time constants (6 seconds). Following the same procedure, you will find the current to be 9.8 amperes at 4 time constants, and 9.9 amperes at the end of 5 time constants.

For all practical purposes the current is considered at full value at the end of 5 time constants.

Study this carefully. Make sure you know how the values were found at each time constant, and then see how they have been plotted on the curve on the next page (Figure 2). You will notice, too, that this curve is an exponential curve.

ASSIGNMENT:

1. If you have a series circuit containing a resistor of 20 ohms and an inductor of 30 henrys, what is the time constant?

2. If the above circuit has 100 volts d.c. applied to it, calculate I_T.

3. How long after the voltage is applied can it be considered that full current is passing through the inductor?

4. How much current is flowing at the end of 1 time constant?

5. How much current is flowing at the end of the second and third time constants?

15266

15267

UNIT XIX - EFFECTS OF CAPACITANCE AND INDUCTANCE

Lesson No. 6 Inductive Reactance

Inductance can be changed by changing the core material in the coil. Any material which provides a better path for the circulation of magnetic lines of flux will cause a coil to have higher inductance. Iron provides a better path for the flow of magnetic lines of force than does air. Therefore, if iron is placed in the center of a coil, the inductance will increase - and so will the inductive reactance.

Inductive reactance is that property of an inductor which reacts against the flow of a.c.

If you connect a coil of many turns of wire in the line of an electric light bulb which is being fed a.c., there will be little if any difference noticed in the brightness of the bulb. If you insert an iron core into the center of the coil, however, the light will dim.

Fig.: XIX-6-1

This is because the iron passes magnetic lines of force better than air does. It is said to have higher permeability than air.

If you connect 110 volts from a d.c. source, the movement of the iron core will have no effect on the brilliance of the lamp.

15268

This inductive reactance (X_L) varies according to the frequency of the current and according to the value of inductance. The formula for finding inductive reactance is

$$X_L = 2\pi fL$$

Inductive reactance is directly proportional to both frequency and inductance. The unit of inductive reactance is the ohm.

ASSIGNMENT:

1. Which material has higher permeability, iron or air?

2. What is permeability?

3. What is inductive reactance?

4. What is the inductive reactance of a 0.5 henry inductor in a 400-Hz circuit?

5. Inductive reactance is directly proportional to the value of inductance. What is meant by directly proportional?

UNIT XX - POWER SUPPLIES

Lesson No. I — Applications

In the early days of radio, when your great-grandfather put aside his crystal set with its catswhisker for a new and modern vacuum-tube set, he had to go to town and buy A batteries, B batteries, and C batteries. The A battery was the battery which furnished the current for heating the tubes. The B battery was the one used for amplifying weak signals into strong signals and for providing the power for his headphones - or maybe even a loud-speaker. The C battery was for furnishing a bias voltage on the grids of the vacuum tubes. The A batteries didn't last very long. Some people used automobile storage batteries for the A battery, and when they became weak they were often carried to the service station to be recharged. Some had their own battery chargers then, but not many.

After a few years of hauling the storage batteries back and forth between home and the service station, someone developed a battery eliminator with wet rectifiers. The radio could now be plugged into the house circuit. Behind the radio were many jars filled with corrosive solutions, which caused many disputes between Grandma and Grandpa about the "looks of the room" or the safety of the children. This went on for quite some time before the dry rectifier was invented. Then Grandpa got rid of his many jars and cleaned up the table where he displayed his radio.

This dry rectifier was actually the forerunner of today's semiconductor of which you hear so much. A rectifier effectively changes alternating current into direct current - that is, a.c. to d.c.

Those old power supplies were used on most radios for quite a number of years - 40 or more - and even now, many receivers still have power supplies incorporated in their circuitry. The majority of radio receivers made now, however, are transistorized and are powered by batteries. The new batteries are light and inexpensive. The heavy A batteries are no longer needed, because transistors do not need heating.

During the development of radio, electronics grew as a new field of industry. This industry started with the improvements and developments in radio, and then came all sorts of navigational equipment for helping those in airships and ships at sea to know where they are. Radar was developed during World War II to detect enemy aircraft. The range of radar was greatly increased and it is being used in many peacetime applications. Atomic energy opened new fields in medical electronics.

15269

15270

We could spend hours discussing the many applications of electronics. In each application we would find that there is some sort of d-c power supply. Some supplies are designed for high voltages and high currents, some for medium power, and some for low power.

LOW

HIGH

Fig.: XX-1-1

MEDIUM

Examples of low-, medium-, and high-voltage power supplies.

15271

Power supplies fall into three categories according to their source of primary power.

1. BATTERY SOURCES. The use of batteries, as previously explained, falls into this category. Also in this class we find the vibrator power supply in which the d.c. from the battery is chopped by the vibrator to permit transformer action in raising the voltage.

   Then, too, there is the dynamotor, which is a d-c motor and generator built together in the same housing. The motor is powered by a battery or batteries and turns the generator amature, which is on the same shaft. Some of the windings are wound together or wound one on top of the other. These dynamotors are designed to develop various voltages and currents.

DYNAMOTOR

Fig.: XX-1-2

2. COMMERCIAL POWER SYSTEMS. This is the kind of power supply we will be talking about in this unit. This is the system where we use the voltages from commercial power lines - the lines which furnish electrical energy to our homes and to our schools. We take this current, rectify it, and filter it so that we can have reasonably pure d.c. at whatever voltage we might need for any particuliar application.

3. ELECTROMECHANICAL SYSTEMS. These are the systems with which some of you will become well acquainted. Into this category fall the many gasoline-powered motor-generators used in military field equipment. Then there are the hand-driven generators. You really hold your transmission time to a minimum when the transmitter is powered by one of the hand-cranked generators!

   The power supply is made up like this: First, the input voltage must be brought to the desired level. This is done with a transformer which can either step up the voltage or step it down. Second, the voltage is then rectified - that is, a d-c voltage is taken out of the rectifier after an a-c voltage is put into it. Third, the rectified voltage is filtered. After rectification, we have d.c., but it is not pure d.c. There is ripple on it, and this must be smoothed.

15271

15272

ASSIGNMENT:

1. What is a power supply?

2. Why are power supplies needed in electronic equipment?

3. What is the function of the rectifier in the power supply?

4. Why is the filter section needed in the power supply?

5. What is a dynamotor?

6. What does the vibrator do in a vibrator power supply?

15273

UNIT XX - POWER SUPPLIES

Lesson No. 2 — Rectifiers

We say that a rectifier changes a.c. to d.c. If you wanted to get fussy, you might dispute this as a literal definition. But this we know: If we put a.c. into it, we can get d.c. out of it. A rectifier will pass a current in only one direction. This means its output is in only one direction. A current which flows in only one direction is called <u>direct current</u> or <u>d.c.</u>

This is the schematic symbol for a rectifier. The arrow head points in the direction of conventional current flow (positive to negative). The arrow head is called the anode, because it is to this end that the positive terminal is connected if current is to pass. The negative terminal is connected to the cathode.

Fig.: XX-2-1

Some manufacturers and writers have made changes in the polarity-symbols. Electrical current is now thought of as flowing from negative to positive (the direction of electron movement). Some manufacturers have changed to the newer convention. It is a good idea to check diodes against their symbol mark with an ohmmeter, so that you will know the direction of current-flow.

If d.c. is applied to a rectifier in the correct direction, current will flow and the meter will indicate voltage.

Fig.: XX-2-2

15274

If the battery's polarity is reversed, no current will flow and the meter will indicate no voltage.

Fig.: XX-2-3

If 60 c.p.s. alternating current is applied, the current will flow during one-half of each cycle and will not flow during the other half. Sixty times during a second the current will flow, and the current will be cut off sixty times during that second.

Fig.: XX-2-4

Note carefully that no current flows during one-half of each cycle. This is important for you to remember, because this is called half-wave rectification. The term "half-wave" is very well selected, don't you think?

Later we shall study full-wave retification, but at this time, let's just look at some of the different types of rectifiers.

You will later learn that radio detectors are really nothing but rectifiers of a special sort. Some rectifiers are made of oxides of metals. Iron rust is an oxide, and it can act as a rectifier under certain conditions. Perhaps you have heard of bed springs and rusty

15275

fence gates giving off sounds from radio stations. That was detection, demodulation, or just plain rectification of the very strong signals of nearby stations through the metallic oxides in these objects.

The copper oxide rectifier has seen much service in many power supplies. The selenium rectifier, which often looks just like the copper oxide type, has had wide usage and is still found in some television receivers. Since some heat is generated by the passage of current through rectifiers, they are constructed with fins to dissipate this heat.

A COPPER OXIDE AND A SELENIUM RECTIFIER

Fig.: XX-2-5

Vacuum tubes were also widely used as rectifiers. You have already learned that electrons will flow from a heated cathode in a vacuum tube to the plate. But electrons will not flow from the plate to the cathode. Can you see how this principle can be used as a rectifier?

Gas-filled tubes are used in many applications where high power is needed. Gas tubes are used because there is very little voltage-drop across the tube while heavy current is flowing. In vacuum-tube rectifiers there is considerable voltage-drop across the tube when current is flowing, and it varies as the current varies.

Today, we use many rectifiers which are so small that they have to be viewed through a microscope. These are on the modern integrated circuit boards. We also have rectifier tubes used in high-power applications that are several feet high and have to be cooled by running water.

Most of the vacuum-tube rectifiers as well as many of the oxide-type rectifiers are now being replaced with solid-state devices. The telephone company and many plants have already replaced bulky rectifiers with much smaller diodes. A diode the size of your index finger can replace a tube-type rectifier the size of your head.

15276

The diode shown below in actual size can replace a vacuum-tube rectifier about the size of a 100-watt light bulb.

Fig.: XX-2-6

ASSIGNMENT:

1. What is a diode?

2. What is a rectifier?

3. What is half-wave rectification?

15277

UNIT XX - POWER SUPPLIES

Lesson No. 3 Transformers

We have been talking about transformers for some time, but we haven't actually studied the transformer.

You know that expanding and receding lines of magnetic force from one conductor will induce a voltage in another conductor if the second conductor is close enough to be cut by the expanding and receding lines. A simple transformer is made of two coils, usually one wound on top of the other, and an iron core placed in the center. The ends of the core are joined to more iron like that in the core. This iron core is a good conductor of magnetic lines of force, and, therefore, gives more efficiency to the transformer. (It is suggested here that you get an old transformer and take it apart so that you can see the segmented core material).

Fig.: XX-3-1

Fig.: XX-3-2

In the simple two-coil transformer, the coil which is connected to the input voltage is called the primary. The coil which delivers the output is called the secondary.

If the primary has 100 turns and the secondary has 200 turns, the output voltage will be twice that of the input. If the primary has 200 turns and the secondary has 100 turns, the output voltage will be half that of the input. The transformer shown in Figure 2 is an iron-core transformer. This is indicated by the vertical lines between the primary and secondary. A symbol for a transformer which does not have these lines is an air-core transformer. Iron-core transformers are used for low frequencies, for power transformers, and audio transformers. Transformers designed for radio frequencies are air-core. A compressed powdered iron core is now being used for frequencies considerably higher than the audio range. These transformers are especially useful where frequencies are above the audio range and where space is at a premium.

15278

Many transformers have several secondary windings so that several different voltage levels may be had from the same transformer. Some transformers have tapped primaries so that the transformer may be used with different values of input voltage.

Most transformers that are used in radio and television have the leads color-coded. Figure 3 shows a commonly used color code.

Fig.: XX-3-3

The output leads, being a.c., will have polarity changes 120 times each second. For instance, for one-half of one cycle (1/120 second) the output will have polarity like this.

Fig.: XX-3-4

During the other half cycle the polarity will be reversed. You will notice that the top lead of the primary and the top lead of the secondary have the same polarity. This will hold true (with this transformer) at all times. This isn't always the way it is. The direction of the secondary turns in relation to the direction of the primary turns determines the polarity of the leads.

In many applications it is not necessary to know the phasing of the leads, but in others it is very important. When the phase-relationship is important, it is equally important that our schematic diagrams show it - and that the transformers themselves show it.

15279

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: III. IGNITION SYSTEM - SECONDARY WIRING

PERFORMANCE OBJECTIVE NO.: 3 TITLE: Remove, Test, and Replace Secondary Wiring

CONDITIONS:

BEHAVIOR:

15. Make thorough inspection and test as outlined in the manual
16. Remove all wires from distributor cap - observe rotation of removal and mark each wire for reassembly
17. Make other tests and inspections as outlined in the manual
18. Rewire distributor cap - observing rotation and identification marks
19. Place wiring assembly on engine and rebolt clamps to engine
20. Place distributor cap on engine making sure that the cap is properly positioned as outlined in the manual
21. Reclip cap to distributor
22. Reconnect each plug wire in accordance to distributor rotation and firing order of the engine
23. Insert coil secondary wire into coil
24. Check all wires to be sure they are firmly in place and that insulating covers are pushed back down on distributor towers and plug insulators

PERFORMANCE CRITERIA:

1523

Figure 5 shows how we represent opposite-direction windings of the two coils. This would indicate that the polarities are out of phase - that is, the two top leads would have opposing polarities.

Fig.: XX-3-5

Fig.: XX-3-6

If you wanted to show this same diagram as an in-phase diagram, you could do it by placing dots as in Figure 6;

or you could reverse the direction of the secondary coil so that both windings would be going in the same direction, as in Figure 7.

Fig.: XX-3-7

Suppose you saw a diagram like this.

Fig.: XX3-8

15279
15280

What would be the value of the output voltage? It would be 0 volts, because reversed polarities have been connected in series. It could be compared to connecting two flashlight cells like this.

Fig.: XX-3-9

The two voltages cancel each other, making the output equal to 0 volts.

There is much more to be learned about transformers before you finish this course. If you want to get "one step ahead," you might go further into the subject before your next year's course. Your instructor will direct you toward good sources of information.

Another type of transformer you should be able to recognize before going any further is the autotransformer ("auto" means "self," or "same.")

Autotransformers
Fig.: XX-3-10

15281

The autotransformer has only one winding, which is both the primary and the secondary. This is the way the connections are made.

Fig.: XX-3-11

The voltage applied to the primary portion of the coil induces voltage into the rest of the coil which adds to the input voltage. A transformer of this type will give a variety of output levels, from 0 volts to approximately a 35% or 40% higher voltage than the input. As a rule, the secondary voltage is seldom more than 35% greater than the input voltage.

There are various sizes and shapes of autotransformers made by numerous manufacturers. One is called a Variac; another company calls its product the Powerstat. It is possible that you will see autotransformers called by other trade names.

Autotransformers are ideal for making adjustments to line voltages when they vary. One disadvantage is that the circuit following the autotransformer is not isolated from the outside line, as it is when a transformer with a separate secondary winding is used.

ASSIGNMENT:

1. Study the diagram of Faraday's demonstration to the Royal Society (Unit XIX, Figure 4-3) and explain its relationship to the study of transformers.

2. Explain mutual inductance.

3. Draw a schematic diagram showing three 6-volt filament transformers connected to give an 18-volt output. Indicate phase in your diagram.

15282

UNIT XX - POWER SUPPLIES

Lesson No. 4 — The Automotive Ignition Coil

Do you recognize the transformer shown in this diagram?

Automobile Ignition System

Fig.: XX-4-1

You have always called this transformer a coil, haven't you? Well, the coil in the ignition system of an automobile is really a transformer.

The battery of a car can supply only d.c. Now how do we get transformer action when we apply d.c.? We have been told that we cannot get transformer action with d.c. This is true. If we put a battery across the primary and hold it there, we will get no continuous voltage from the secondary. (In fact, we might burn out the primary winding.)

If you have a voltmeter across the secondary and apply d.c. to the primary, you will see the needle jump when you first make contact, but it will go back to zero until you break the connection; then it will jump in the opposite direction. It is only while the lines of magnetic flux are cutting the secondary turns that we have a voltage induced.

15283

When you make the connection, the magnetic lines of flux start from the conductor and spread out.

Fig.: XX-4-2

When you break the connection, the lines collapse and move back toward the conductor (the wire in the primary).

Fig.: XX-4-3

In the ignition transformer (the coil), the turns-ratio is such that 12 volts (or 6 volts) on the primary will produce about 20,000 volts across the secondary. This high voltage is necessary to produce a spark large enough to ignite the fuel mixture in the combustion chamber. Some cars have between 25,000 and 30,000 volts on the spark plugs.

A capacitor is placed across the switch (the points) to eliminate excessive arcing, which burns out the points. This arcing is almost completely eliminated in the transistorized ignition systems, where the points are not required to make and break the current going to the coil. In these systems, the points merely switch a low-current voltage on and off the transistor, which switches the coil current on and off.

ASSIGNMENT:

1. What do the points do in an ignition system?

2. Why are the points necessary?

3. What is the potential supplied to the spark plugs?

4. Why is it necessary to have such high voltages on the spark plugs?

5. How is this high voltage developed?

12583

-15284

UNIT XX - POWER SUPPLIES

Lesson No. 5 — Full-wave Rectification

You have been taught to think of current as going from negative to positive. There are several reasons for this which you understand by now. During the study of crystal diodes, however, it is better to think in terms of conventional current flow (positive to negative), since the research scientists who did pioneering in crystals think in conventional directions. These are the men who created the symbols which you see in schematic diagrams with their arrowheads pointing from positive to negative.

As you know, when a diode is placed in an a.c. circuit, current can flow during only one-half of the cycle.

Fig.: XX-5-1

During the other half-cycle, when the polarity of the a.c. input is reversed, the current will not flow, due to the fact that the diode will pass the current in only one direction. This is half-wave rectification, and with this type of rectification, in a 60 c.p.s. line, current will flow for 1/120 second and be off during the next 1/120 second.

Fig.: XX-5-2

It doesn't take too much reasoning to understand that there must be some advantage in having the current flow during these "no current" times. For one thing, it greatly reduces the ripple of the current. This can be arranged by using another diode. This is called full-wave rectification.

15285

Let's study the following diagram.

Fig.: XX-5-3

As you know, when S_1 is positive, S_2 will be negative, and during the next half-cycle this will be reversed. Any time S_1 is positive, the center tap will be negative in respect to S_1; and any time S_2 is positive, the center tap will be negative in respect to S_2.

Let's assume now that S_1 is positive. Current will flow through D1, then through R_L to ground and from ground to the center tap, completing the circuit. On the next half-cycle, S_2 will be positive, so the current will flow through it, through R_L to ground; and then from ground it will flow to the center tap, completing the circuit during this half-cycle.

Now you can see how the current is flowing through the load resistor at all times. In half-wave rectification, it flows only half the time.

Note the output waveform. It is not flat on the top exactly like d.c. from a battery, is it?

ASSIGNMENT:

1. Why does current flow for only half the time in half-wave rectification?

2. What is full-wave rectification?

3. Draw a half-wave rectifier.

4. Draw two full-wave rectifiers (one for each half-cycle) and show the path of current-flow in each.

15286

UNIT XX - POWER SUPPLIES

Lesson No. 6 — Filters

You saw in the previous lesson that the waveform as it comes from the rectifier is not flat, as it would be when coming from a battery. The varying current is d.c., though, because it goes in one direction only. However, there is ripple on it. Let's look at this ripple again.

Fig.: XX-6-1

You can see that you have a positive voltage, but it is varying in value from +90 volts to +110 volts. (Note: a simple rectifier would vary from 0V to 110V). These are the tops of the full-wave peaks — 120 per second. If you place a capacitor across the output,

Fig.: XX-6-2

15287

it will charge to 110 volts when the output voltage is at its peak, and will try to hold that voltage during the time that the voltage is 90 volts. Instead of being like part A of Figure 3, we will have something like part B.

Fig.: XX-6-3A

Fig.: XX-6-3B

You can see that the capacitor is keeping the voltage from dropping below 100 volts now.

If you put an inductor (called, in this application, a filter choke) in series like this

CHOKE-INPUT FILTER
Fig.: XX6-4

15287

15288

the output voltage will be smoother still. You remember that an inductor resists changing current. This ripple frequency — changing, in this example, from 90 to 110 volts — causes a corresponding change in the current, so the choke smoothes a little more of the ripple out of the output voltage. Some better filter circuits have two chokes and two capacitors in what is called a double-section filter, as shown in Figure 5.

Fig.: XX-6-5

Filters such as this, when the proper values of inductance and capacitance are used, deliver d.c. outputs of almost battery-quality d.c.

If a filter is connected as in Figure 6,

CAPACITIVE-INPUT FILTER

Fig.: XX-6-6

it is known as a capacitive-input type and has the disadvantage of having poor regulation — that is, dropping in voltage as load is applied. If it is a choke-input filter, as shown in Figure 4, the voltage will be slightly lower, but the regulation will be better.

In the choke-input type, the choke tends to resist changes in current values (due to back e.m.f. in the inductor) and reduces the peaks before the capacitor gets a chance to store them.

15289

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: III. IGNITION SYSTEM - SECONDARY WIRING

PERFORMANCE OBJECTIVE NO.: 3 TITLE: Remove, Test, and Replace Secondary Wiring

CONDITIONS:

BEHAVIOR:

25. Check to make sure engine compartment is clean of rags, tools, materials, etc.
26. Start engine
27. Make tests and inspections as outlined in the manual
28. If engine performs satisfactorily, replace air breather assembly
29. Clean and replace tools and materials
30. Remove fender covers and store in proper place
31. Close hood
32. Return automobile to proper parking area
33. Remove seat covers and store in proper place
34. Clean work station for next project

PERFORMANCE CRITERIA:

To be able to satisfactorily remove, test, and replace secondary wiring in $1\frac{1}{2}$ hours

Learning time: 3 hours

1524

In the capacitive-input type, regulation is poor because of the capacitor's inability to hold the complete charge until the next half-cycle when it is charged again. Therefore, where good regulation is required, it is best to use the choke-input-type filter.

Figure 7 shows a typical full-wave power supply with filter.

Fig.: XX-6-7

ASSIGNMENT:

1. Draw two schematic diagrams of a typical center-tap-type full-wave rectifier power supply. On one trace the conventional current-flow for one half cycle, and on the other diagram show the path of the current during the following half cycle.

2. How does capacitance in the power-supply filter aid in filtering out the ripple?

3. Describe the part the choke plays in filtering ripple.

15290

UNIT XX - POWER SUPPLIES

Lesson No. 7 — The Bridge Rectifier

The full-wave power supply described in Lesson 6 utilized a center-tapped secondary like this.

Fig.: XX-7-1

Only a half of the secondary winding is used at any one time, as you remember. In a secondary like the one above, only 350 volts can be obtained. There is another type of circuit which makes it possible to get the full 700 volts from the secondary. That is the <u>bridge type</u>. With the bridge you will get an output of twice the voltage, but only half as much current may be drawn as in the center-tapped circuit (where you get half the voltage).

If a transformer's maximum output with the center-tapped circuit is 350 volts at 200 MA, that means that the maximum power is 350 x 0.2, which gives us 70 watts. If you were to draw the same current at 700 volts, that would be 140 watts. If 70 watts is the maximum power, then it is impossible to draw 140 watts, isn't it?

Now that we know that you can get twice the voltage but only half the current when we use a bridge circuit instead of a center-tapped circuit, let's look at the bridge circuit.

Fig.: XX-7-2

15291

The top terminal is negative and the bottom terminal is positive, as shown in Figure 3. *Remember we are thinking in terms of conventional current flow.*

Fig.: XX-7-3

The small arrow heads point out the path as well as the direction of current flow. In Figure 4, the polarities are reversed. Follow the path and the direction now.

Fig.: XX-7-4

The bridge-type full-wave rectifier is most convenient in giving higher voltages when modest amounts of current are needed. This type of rectifier circuit also needs a filter, just as the center-tap full-wave rectifier does, and the same filter considerations are required.

ASSIGNMENT:

1. Draw two separate bridge rectifiers (one for each half-cycle) and trace the path of electron current flow through each.

2. What is the advantage in using a bridge-type rectifier? What could be a disadvantage?

15292

GLOSSARY

ACCELERATION The speeding up of velocity. The speeding up of electrons by an accelerating anode in a cathode-ray tube. Electrons are usually focused by the first anode in a CR tube and then are accelerated when they go through the opening in the second anode.

ADJACENT Adjoining, next to. *His property was adjacent to the park. A current was induced into the adjacent turn of the coil.*

ADJUSTABLE Capable of being adjusted or changed. *He is using an adjustable wrench. He changed the voltage by moving the collar on the adjustable resistor.*

ALGEBRAIC Pertaining to algebra. *He wrote an algebraic equation. Algebraic equations and algebraic addition are used in solving problems by Kirchhoff's laws.* In algebraic addition, the numbers may have either positive or negative signs. Example: -2 +4 -7 = -5

ALKALI (pl. alkalis or alkalies) A substance which, chemically, is the opposite of an acid. Lye and soda-ash are alkalis. They may be neutralized by acids or they may, on the other hand, neutralize acids. (The adjective form of the word is ALKALINE. *The soil in your yard may be alkaline or it may be acid.)*

ALTERNATION A change to the other condition. In electricity, the changing from positive to negative or from negative to positive. An alternation is a single change. If the change is from positive to negative and then back to positive, this is a cycle. There are two alternations in a cycle.

AMMETER An electrical meter for measuring electric current.

AMPLIFICATION Making something larger or greater.

ANALYSIS The act of finding the nature, value, or function of something by thorough examination of its parts.

ATOMIC Pertaining to atoms, or referring to something very small.

ATTRACTION The mutual action by which bodies or particles tend to come together.

AUDIO 1.Pertaining to electromagnetic waves that correspond to sound waves that are within the range of hearing (15 to 20,000 cps). 2. In television broadcasting, that portion of the signal which carries the sound rather than the picture.

15293

CAPACITOR An electrical device consisting of two or more plates of a conductive metal separated by an insulating material called a dielectric. This device, sometimes called a condenser, stores an electric charge.

CENTIGRAM A unit of weight equal to 1/100 gram; abbrev. cg.

CHEMICAL A substance used in a chemical operation or produced by such an operation.

CHEMISTRY The science dealing with the composition and properties of different kinds of materials.

COMMUNICATION Giving and receiving information by audible, visual, or electrical means.

COMPLEX Complicated; not simple. Also (noun), a whole thing made up of a great number of related parts.

COMPONENT A part of a whole. *A transformer is one of the components of a power supply.*

CONDUCTOR In electricity, a substance or material that readily transmits electricity. There are other conductors, such as those materials which conduct heat, sound, etc.

D'ARSONVAL MOVEMENT A type of meter movement, also called the moving-coil-type movement. This movement is commonly used in most multimeters and test equipment.

DIELECTRIC An insulating material between the plates of a capacitor. Air, mica, paper, and oil when so used are dielectrics.

DISCHARGE To relieve of a charge, to fire off, to give forth, emit. Also (noun), the release of stored energy.

DYNAMO A machine for converting mechanical energy into electrical energy; an electric generator. Sometimes loosely used for a machine that converts electrical energy into mechanical energy.

DYNAMOMETER An apparatus for measuring force. The term is now used for numerous testing devices - some very elaborate systems - for testing machines under operating conditions.

EFFICIENCY The ratio of output to input. In electrical and mechanical technology, this term is the ratio of the output to input power, expressed in percentage. If 100 units of a quantity goes in and only 50 units come out, the efficiency is 50/100 or 50%.

15294

FILAMENT A threadlike object; the wire which glows in an electric light or which heats a radio tube.

FREQUENCY The number of times a thing is repeated in a given unit of time. Example: The current in a circuit reverses its direction and then returns to its original direction (two changes) sixty times per second (120 changes). *Its frequency is 60 cycles per second, or 60 Hz.* Symbol, f.

GENERATOR In electricity, any machine by which mechanical energy is changed into electrical energy; a dynamo, especially a large one.

HENRY The basic unit of electrical inductance.

IGNITION Act of igniting (setting fire to something); also, means of ignition.

INDUCE 1. To bring on or about. 2. To produce by induction, as an electric current.

INDUCTION The process by which an electrical conductor becomes electrified in the presence of an electrically charged body or a magnetic field. A magnetizable body can similarly be magnetized by induction by being in a magnetic field.

INDUCTOR A part of an electrical apparatus which acts on another part, or is itself acted on, by induction. A coil of wire is an inductor, since it acts upon alternating current with inductive reactance.

INSTRUMENT A device for doing work or producing an effect.

INVERSE Opposite in order, relation or effect; reversed; inverted. Example: $X_C = \frac{1}{2\pi f C}$. Frequency (f) is inversely proportional to X_c, because, as f increases, X_c decreases, and as f decreases, X_c increases.

ISOLATE To set apart from others; place alone. *In electricity, the secondary of a transformer is isolated from the primary as far as d.c. is concerned.*

JUNCTION A place of joining, a place where an electrical connection is made to another part of the circuit or to another circuit.

KILOMETER A unit of length or distance, equal to 1,000 meters or approximately 5/8 mile. This unit is used in continental Europe.

MAGNITUDE Greatness of size, importance, influence. *We use meters, in electricity, to learn the magnitude of the resistance or current or voltage.*

15296

MANUFACTURER A person or organization of persons engaged in the making of a product.

MERCURY A heavy, silvery metallic element which is liquid at ordinary temperatures. It is sometimes called quicksilver. The chemical symbol is Hg. It is used in thermometers. Dentists mix it with other metals for filling teeth.

MEGOHM 1,000,000 ohms

MICROFARAD A unit of measurement of electrical capacitance equal to 1/1,000,000 farads or 1×10^{-6} farads.

MILLIHENRY A unit of measurement of electrical inductance equal to 1/1,000 henry or 1×10^{-3} henry.

MODULATE In radio, to vary the frequency, phase, or amplitude of a radio wave according to an audio frequency. Or, to apply sound-wave signals to change some characteristic of a transmitted radio wave.

MODULATION In radio, the variation of a radio frequency by applying audio frequency.

MOLECULAR Pertaining to, consisting of, or produced by molecules.

MOLECULE The smallest particle of an element or compound that can exist in the free state and still have the characteristics of that substance.

MULTIMETER A meter for measuring more than one of the quantities of electricity or electrical effect. Example: a meter which measures volts, amperes, and ohms.

MUTUAL Having a similar effect, one on another. *A mutual dislike; mutual induction.*

NUCLEUS A central thing or part around which other parts or things are grouped. In chemistry and physics, the central part of an atom, containing practically all the mass (weight) of the atom. *Electrons are usually pictured as rotating about the nucleus of the atom.*

OHM The unit of electrical resistance, equal to the resistance of a circuit in which an electromotive force of one volt maintains a current of one ampere.

OSCILLATOR In electronics, a circuit which causes variations between maximum and minimum values of current and voltage. These variations may alternate between maximum positive and maximum negative. The frequency may be very low or very high. The RF carrier signal of a transmitter originates in an oscillator. Oscillators, both audio frequency (AF) and radio frequency (RF), are used in many test applications, and are sometimes called signal generators.

15297

220 OF 327

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

OSCILLOSCOPE A device that shows periodic changes in an electric quantity on the fluorescent screen of a cathode-ray tube. These presentations may then be studied for shape, frequency, magnitude, etc.

PARALLEL Extending in the same direction and at a constant distance apart.

PERMEABILITY In electricity, the ability to concentrate magnetic flux. *Soft iron has high permeability because it is very effective in concentrating magnetic lines of force.*

PHYSICS The science dealing with the properties, changes, interaction, etc. of matter and energy.

PITH The soft, spongy tissue in the center of certain plant stems.

POLAR In electrical science, having polarity. Having two opposite natures, directions, etc. (Literally, on or near the North or South Pole.) *In checking the polarity of the current, I found that I had accidentally attached the positive wire to the negative terminal.*

POLARIZATION The producing or acquiring of polarity, as the inducing of north and south poles into a bar of iron.

POTENTIAL 1. That which can be but has not yet come into being; possibliity. 2. In electricity, the relative voltage between two points in an electrical circuit.

POTENTIOMETER A three-terminal variable resistor.

PREFIX One or more letters or syllables added at the beginning of a word to modify its meaning. For example, meg in megohm changes the word ohm to a word meaning one million ohms.

PRIMARY First in order of development, time, or intention. Electricity: In a transformer, the word refers to the coil into which the input current flows.

PRINCIPLE A fundamental or general truth. A general or settled rule of action.

PROTON Positive particle in an atom. The smallest quantity of positive electricity that can exist in a free state.

PYTHAGOREAN Of or pertaining to Pythagoras, a Greek philosopher. The Pythagorean theorum, Hyp = $\sqrt{h^2 + b^2}$, gets its name from Pythagoras.

RADAR (RAdio Detection And Ranging) A device for locating an object by measuring the time for the echo of a radio wave to return from it, and the direction from which it returns.

10. The Starter	10. Teaching machine cards 5A & 5B	4. Teaching Machine (Shop)

RATIO One value divided by another of like kind; usually expressed as a fraction. It tells the relationship between numbers. *The ratio of 75 to 100 is the same as the ratio of 3 to 4.*

REACTANCE In electrical circuits, reactance is the opposition of inductance and capacitance to alternating current. The symbol for reactance is X. Reactance is measured in ohms.

RECTIFICATION In electricity, the conversion of alternating current into one-directional current by means of a rectifier.

REPULSION Mechanical force tending to separate bodies having like electrical charges or like magnetic polarity.

RESISTANCE Property of a conductor which determines the amount of current that will flow as a result of the application of a given electromotive force.

RHEOSTAT A resistor whose value can be varied.

SCHEMATIC DIAGRAM Circuit diagram in which component parts are represented by simple, easily drawn symbols. Sometimes simply called the schematic.

SECONDARY Next below the first in importance; one in a subordinate place. In electricity, the output coil in a transformer.

SELENIUM Chemical element having marked photosensitive properties and a resistance that varies inversely with illumination. Selenium is also used in contact with iron to form the selenium rectifier.

SENSITIVITY Least input capable of causing a desired output.

SERIES A number of similar things or events standing or following each other in order. In electricity, the method of arranging the components in a circuit by connecting them end to end to provide a single path for current.

SHUNT To turn to one side. Electricity: 1. A precision, low-value resistor placed across the terminals of an ammeter to increase its range. 2. Any part connected in parallel with some other part. Or the act of connecting a part in parallel with some other part.

SIMULTANEOUS At the same time.

SOURCE Origin; first cause. *A battery is the source of electricity in some circuits.*

15299

STATIC Not changing, lacking movement. Electricity: 1. Referring to the electricity of charged bodies. 2. Interference in a circuit. Static may come from either natural disturbances, such as lightning or northern lights, or from nearby electrical equipment, usually due to some fault. 3. A fixed, non-varying condition, as those used to make certain tests known as static tests.

SUPERHETERODYNE RECEIVER A radio receiver in which a local oscillator creates a signal to be mixed with the incoming signal to produce another signal of a lower frequency. This new signal, called the IF signal, is the result of heterodyning or beating the two signals together. The IF signal undergoes high amplification in the IF amplifier stages and is then fed into a detector (the second detector) for demodulation. The signal from the second detector is then usually further amplified for power.

TECHNICIAN One highly skilled in the basics of a certain technical field and often highly trained in the physics and mathematics of that field. In industry, the technician interprets the engineer's language and directives to the production personnel.

TERMINAL Last, end, final. The final station in a radio relay system is called the terminal station. In electricity, a fitting to which electrical connections are made.

THEORY A general principle offered to explain certain facts.

TOROIDAL Shaped like a doughnut.

TRANSFORMER An electrical device, without moving parts, which by electromagnetic induction transfers electric energy from one or more circuits to one or more other circuits at the same frequency, usually with changed values of voltage and current.

TRANSMISSION 1. The transfer of electric power from one location to another through conductors. 2. The dispatching of a signal by wire or wireless.

TRANSISTOR A minute electronic device, used like an electron tube, which controls current-flow by means of a semiconductor, such as germanium.

VARIABLE Changing, changeable.

WHEATSTONE BRIDGE A null-type resistance-measuring circuit in which resistance is measured by direct comparison with a standard resistance. This circuit was devised by Samuel H. Christie, 1784-1865, English scientist and mathematician, and was introduced to the scientific world by Sir Charles Wheatstone, 1802-1875, English scientist and inventor.

UNIT XIII

ACHIEVEMENT TEST

1. Write the equations for I_1 and I_2 in the following circuit.

2. From the following two equations, find the value of I_1.

$$20I_1 + 30I_1 + 30I_2 + 60I_1 - 50 = 0$$

$$30I_2 + 10I_2 + 10I_1 + 20I_2 - 80 = 0$$

3. From the following two equations, find the value of I_1.

$$30I_1 + 20I_2 - 90 = 0$$

$$60I_1 + 10I_2 - 30 = 0$$

4. From the equations in problem 3, find the value of I_2.

5. State Kirchoff's first law in your own words.

15309

UNIT XIV

ACHIEVEMENT TEST

1. How did the magnet get its name?

2. What is Alnico?

3. If a coil of 1200 turns has a current of 3 amperes flowing through it, what is its magnetomotive force?

4. Explain in your own words the molecular theory of magnetism.

5. Who was Hans Christian Oersted? What did he do?

6. Draw a cross section of a wire, indicate the direction of an electric current going through it, and show the direction of magnetic flux around it.

7. What does the letter H denote?

8. What is a gilbert?

9. Give three precautions for preserving the strength of a permanent magnet.

10. What is field intensity?

15210

UNIT XV

ACHIEVEMENT TEST

1. What type of meter movement is the most commonly used?

2. Give another name for the movement mentioned above.

3. Is the movement mentioned above a current-or voltage-operated device?

4. How many coils are there in the electrodynamometer movement?

5. How does the electrodynamometer movement compare with the commonly used movement mentioned in No. 1 in (a) sensitivity, (b) accuracy?

6. Explain the principle of operation of the iron-vane type of meter movement.

7. What are the principles on which the thermocouple-ammeter works?

8. For what types of measurements is the bolometer usually used?

9. Is the electrostatic voltmeter a current-or voltage-operated device?

10. What type of meter movement does not have a linear scale?

11. How is the sensitivity of an ammeter rated?

12. How is the sensitivity of a voltmeter rated?

13. Name the two purposes for which the galvanometer is used.

15311

UNIT XVI

ACHIEVEMENT TEST

1. Why are meter rectifiers placed in voltohmmeters?

2. Is the rectifier needed in the d.c. voltmeter circuit?

3. Why are multiwafer rotary switches used in voltohmmeters?

4. What is the principle difference between a d.c. voltmeter and an a.c. voltmeter?

5. Why is there a battery in a VOM?

6. Generally speaking, how are the resistors placed in the ammeter circuit?

7. How many different kinds of measurements can one accomplish with a VOM?

8. Why should every electronics technician have a VTVM?

9. What do the letters in VTVM stand for?

10. In a vacuum tube, what controls the flow of electrons?

15312

UNIT XVIII

ACHIEVEMENT TEST

1. What is reactance?

2. How are capacitive reactance and inductive reactance related to each other?

3. Will d.c. pass through a capacitor?

4. How does inductive reactance affect the flow of d.c.?

5. If a 2-henry inductor is placed in series with a 60-cps circuit, what is the X_L?

6. If an electric heater draws 5 amperes from a 110-volt line, how much power is it consuming?

7. Explain why power transmission lines carry a.c. rather than d.c.

8. How much current is being drawn by a 150-watt light bulb when it is connected to its rated voltage of 110 volts?

9. In the field of electronics, what does the Greek letter lambda stand for?

10. What is the frequency of a 20-meter radio signal?

15313

UNIT XIX

ACHIEVEMENT TEST

1. Draw a rough graph showing two different progressions, one linear and the other exponential.

2. Explain what a dielectric is and what happens to the atoms of the dielectric when a capacitor is holding a charge.

3. What is a capacitor? What kind of functions does it perform, and what does it do in performing its functions?

4. What is the unit of capacitance?

5. What part of a farad is a microfarad?

6. What is a micro-microfarad?

7. What is a picofarad?

8. What is capacitive reactance?

9. In what units is inductance measured?

10. In what units is inductive reactance measured?

11. What is the X_L of a 60 Hz circuit which has inductance amounting to 1.18 henry?

12. If the above circuit also has capacitance amounting to 6 μf, what is the overall reactance?

15314

UNIT XX

ACHIEVEMENT TEST

1. What are power supplies? Why are they needed?
2. What does a rectifier do?
3. Name two kinds of rectifiers - the devices, not the circuits.
4. How does a vibrator power supply operate?
5. What is half-wave rectification? Explain and draw a circuit.
6. What is a semiconductor material?
7. Draw the symbol for an autotransformer and explain how it works.
8. What is full-wave rectification?
9. What is regulation?
10. Draw a bridge-type full-wave rectifier.

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: IV. STARTING MOTOR

PERFORMANCE OBJECTIVE NO.: 4 TITLE: Remove, Disassemble, Reassemble, Replace, and Test Starting Motor

CONDITIONS:

This assignment is to be performed on a complete automobile.

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective covers on front seat of automobile
2. Move automobile into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper manual and turn to appropiate chapter
6. Select proper tools and materials
7. Disconnect battery ground cable
8. Disconnect battery to solenoid cable from battery
9. Position support arms under automobile and carefully raise automobile with floor lift to desired working height
10. Remove starter terminal nut and remove starter cable
11. Remove starter to clutch housing bolts
12. Remove starter by bringing forward until bendix drive clears starter ring gear then lower fron under automobile

THE SUPERVISION AND TRAINING OF CASE AIDES IN PUBLIC WELFAR

Introduction

A major effort is currently being undertaken by a number of agencies to restructure job assignments so as to achieve tw comes from a recognized need to enrich and expand social se stresses the need for an expanded use of different classifi providing agency program services to clients. The second g recognition that large groups of individuals, and particula tofore been denied access to employment in the human servic meaningful job opportunities, which provide training and ca nities for welfare recipients and other poor persons, place upon the human services field to define meaningful employme opportunity for such persons to enter employment through ag The unique skills of the professional, in short supply, can priately used to maximum benefit when those tasks he now pe or utilize his education, are delegated to other staff who performing these as members of an agency service team. In which preprofessional staff members can perform which have vided to agency clients due to a lack of sufficient staff t

The purpose of this reference is to look more closely at th Aide in public welfare, and particularly to summarize from ture, the knowledge and some of the principles which have be to the training and supervision of these new staff members, services field, in general, as well as in public welfare it and supervision of Case Aides in public welfare is likely t of whether this opportunity to employ preprofessionals wil adding new and necessary dimensions to the agency's program question of the ability of preprofessionals to contribute t based upon the experiences of many other agencies in recent

15326 15323 325

PERVISION AND TRAINING OF CASE AIDES IN PUBLIC WELFARE

uction

r effort is currently being undertaken by a number of governmental and private
es to restructure job assignments so as to achieve two major goals. The first
from a recognized need to enrich and expand social services to clients and
es the need for an expanded use of different classification levels of staff in
ng agency program services to clients. The second goal comes from increased
tion that large groups of individuals, and particularly the poor, have here-
been denied access to employment in the human services. The need to open
gful job opportunities, which provide training and career advancement opportu-
for welfare recipients and other poor persons, places heavy responsibility
e human services field to define meaningful employment tasks, and to provide
nity for such persons to enter employment through agencies like public welfare.
que skills of the professional, in short supply, can only be said to be appro-
y used to maximum benefit when those tasks he now performs, which do not require
ize his education, are delegated to other staff who are equally capable of
ning these as members of an agency service team. In addition, there are services
reprofessional staff members can perform which have not been previously pro-
o agency clients due to a lack of sufficient staff time and resources.

pose of this reference is to look more closely at the new role of the Case
public welfare, and particularly to summarize from the professional litera-
e knowledge and some of the principles which have been developed in relation
training and supervision of these new staff members, within the broader human
s field, in general, as well as in public welfare itself. Because the training
ervision of Case Aides in public welfare is likely to be the prime determinent
her this opportunity to employ preprofessionals will truly provide a means of
new and necessary dimensions to the agency's program - for there can be little
n of the ability of preprofessionals to contribute to such an achievement,
pon the experiences of many other agencies in recent years - the line

15325

ervisor must assume an important teaching role, necessary to the preparation of a ningful place for the Case Aide as a member of an agency team which is responsi- for the provision of defined program services to a specific group of clients.

ial Welfare Manpower Needs

hough major efforts have been made since 1962, to increase the number of graduates professional schools of social work, primarily through provision of educational ve stipends, public welfare agencies have increasingly come to realize that these orts alone will not solve the "manpower crisis" in which the agency has been al- t continuously involved since 1962. Obviously, the solution of manpower problems t be found elsewhere. To some extent, the employment of workers with baccalau- te degrees to provide public welfare program services to clients earlier reflected inistrative realization that sufficient professional manpower, with an MSW degree, ld probably never be available to fill all social service positions within the ncy. More recently, many persons have asked whether the agency would want, even the best of possible worlds, to employ MSW's to fill many of these positions. iously, it would not because many public welfare services can be provided by sons with less education. However, the analysis of various tasks to be performed achieving program goals has yet to be accomplished, so that clearer delineation the tasks to be performed by the MSW, the baccalaureate degree worker and various e aide classifications can be identified. The primary solution to manpower blems in public welfare, as in other human service agencies, must ultimately be nd in the creation of a continuum of classification levels of staff, with respon- ilities clearly differentiated at each level of professional development - a tem wherein the expertise of each employee is recognized and fully utilized.

relieving professional workers with an MSW or a baccalaureate degree of tasks t do not require professional education at either a graduate or undergraduate el for their performance, the agency will be opening the door to a more efficient effective use of professional staff time and an improved level of practice in provision of program services. Thus, the differential use of staff which is lected in the new careers for the poor concept must, if it is to be fully realized,

ntually result in new careers for the professional as well. For example, the e of the social service worker, when several employees have direct and simul- eous contact with an individual client, must necessarily differ markedly from previous responsibilities for sole relationship in the helping process - instead cing emphasis on a larger purview of the helping relationship by adding the iprocal influence of auxiliary helping roles. Thus, rather than relieving the ial service worker of the need for skill in the use of relationship, it will uire him to sharpen his perception of his own role and to use his skills more posefully with the client, the total agency work group and those members of ff designated as carrying specific service functions. It will center him in a dership role in the delivery of program services.

New Career Concept and Its Implication for Public Welfare

proposed and developed by Pearl and Riessman, the "new career concept" begins h the premise that there is a need to create new jobs within the human services; that these jobs will involve the assignment of a number of tasks normally allotted more highly-educated professional or technical staff, but which can be performed by atively unskilled, inexperienced persons, and assigning these to preprofessionals, ruited from among recipient groups. Hiring the poor to serve the poor is certainly undamental and logical approach to the problem of poverty within a highly automated iety, partly because these jobs are less likely to be automated out of existence partly because of the need to provide vastly improved and enriched services for se members of our society who are in need of agency intervention. There are many ntified needs which social agencies have been unable to meet within the limitations current manpower resources. Preprofessionals can, especially in these areas, provide ded manpower resources and contribute to expanding the vast array of services required an automated and industrial age.

viding jobs for the poor which they can perform must be only the first of a number of os taken in implementing a new career concept. These jobs must be made permanent; y must become a meaningful and intricate part of the agency system; and they must vide opportunity for advancement through a multi-level lattice of positions. Advance- t through a series of positions requiring the performance of increasingly complex more responsible tasks of a related nature is to be an agency goal. Such a lattice nt eventually provide a continuum of positions ranging from nonskilled entry level

signments, continuing through intermediate nonprofessional functions, an assistant sition (two years of college plus experience), a worker position (four years of llege plus experience), and finally terminating in a recognized professional posi-on (requiring graduate education). Thus, if this concept is to be fully implemented, e will eventually see the development of separate career ladders within social ser-ce, within income maintenance, and within specialized technical functions, with an portunity for vertical advancement, as well as horizontal transfer in those situations ere an individual's skills can most effectively be developed in an area other than the e to which he is currently assigned.

e new career concept and its application within the public welfare system must even-ally involve the adoption and implementation of four major administrative strategies, y one of which will individually determine whether the agency's goal of a differential aningful use of staff will succeed or fail. Briefly, these four strategies will clude:

1. The employment, training, and use of preprofessional staff in newly created job assignments to perform social service tasks and functions which are based on redefined social service goals.

2. The total restructuring of job assignments at various classification levels of staff, to assure maximum use of professional education at both a graduate and undergraduate level, and employment experience.

3. Adoption of a social service team approach wherein several members of staff. will work together to achieve the social service goal for and with the client (and in variance with past emphasis upon the single social service worker's assessing client need and performing all necessary agency activi-ties to meet this).

4. Expansion of the opportunities for upward mobility of all staff members, including the planned use of both inservice training and part-time use of educational leave.

15331

The Use of Case Aides in the Human Services

Because of the relative newness of preprofessionals as team members in the delivery of social services, there are yet no clearly defined boundaries within which case aide activites should occur. Instead, each agency has faced the task of defining preprofessional responsibilities in terms of its own program of services to clients, while differentiating case aide functions from those to be performed by other classification levels of staff. Because of the wide range of skill, education, and life experiences with which case aides come to the agency, their specific assignments, and particularly the early tasks which they are asked to perform, will largely be determined by the specific abilities of the individual aide, within the broader program definitions of functions which have been identified.

Studies which have been done in the area of social service task assignments suggest that most tasks performed by preprofessionals can be grouped under four broad categories of responsibility:

1. Direct service responsibilities usually involve aspects of counseling, remediation, job development, tutoring and teaching. Such assignments tend to make maximum use of preprofessional skills in specific areas and attitudes, such as "enthusiasm, spontaneity, ability to communicate with clients through common language or style, empathy, and ability to help clients to negotiate the complexities of the ghetto."* Within county public welfare departments in California, such direct service responsibilities have frequently taken the form of showing, demonstrating, and advising clients on such matters as food preparation and buying, household management, and budget planning.

2. Joint responsibilities, ancillary to the provision of other agency services, usually aim more specifically at bringing the client and the service into more productive contact. Within county public welfare departments in California, such joint responsibilities may involve the Case Aide in securing information from clients, needed (by an eligibility worker) in determining or redetermining eligibility for financial assistance; or in escorting a hesitant client (who is being seen by a social service worker) to, from and through the use of a specific community resource already determined to be needed by the client.

3. Bridging responsibilities involve activities which help to relate the agency to a larger target population, rather than to an individual client. For example, in California county public welfare departments, such activities may take the form of explaining and advising clients (or groups of clients) on the use of resources within the county department; or locating and meeting with established neighborhood groups which have neighborhood improvement goals, to provide information about the agency.

4. Recruitment and follow-up responsibilities involve activities which aim at locating potential clients or potential users of a specific program from among an already identified client group. For example, in California county public welfare departments such activities may involve the Case Aide in advising and assisting a particular client to make an initial request for agency social services.

Legislative Trends

The use of preprofessionals in the provision of social services is not a new idea. There is precedent for such programs, previously during World War II, and more recently in numerous experimental and demonstration projects. For many years, institutions have made use of different classification levels of staff in providing care and services to their client population, even if the more traditional community social agency has tended to move somewhat slower in recognizing the potential contribution of preprofessionals to direct service activities. Probably the enactment of the Economic Opportunity Act of 1964 has contributed most to the development of a new careers concept, because of its emphasis upon maximum participation by the poor, and the involvement of the consumer of services in planning and deciding how such services are to be provided. The following year saw the publication of Arthur Pearl's and Frank Riessman's book, New Careers for the Poor. This publication, more than any other, in defining this concept, has provided the needed direction necessary to planning and implementing new careers programs.

In 1966, the first major legislation was passed directly implementing a new careers program. In amendments to the Economic Opportuity Act, a new program was established (Title II, Sec. 205, e) to prepare low-income persons to enter career employment in

lic services. This "Scheuer Amendment" marked congressional commitment to the a that "new careers for the poor" was to be a major thrust toward creation of loyment opportunities for those previously denied access to public service oc- ations. In the 1967 amendments to this same act, the language as well as its visions were further strengthened and, in congressional reports, stress was e of the need to assure job opportunities for those who are trained. The ate report stated:

> "The new careers program is too new for evaluation. However, the committee notes that while the early emphasis is upon training, which is proper, it appears that not enough attention is being given to assure that 'new career' jobs, paid by other funds, will be available at the completion of training. It will not be easy to break down traditional barriers, such as civil service regulations and profes- sional 'standards', which block the disadvantaged from moving into public service occupations, but considerable effort must be made in this regard if the program is to succeed."

as of surprise to very few persons when, in the Social Security Amendments of , this same commitment to a new career concept was specifically implemented in ic welfare. At this time, the training, employment and use of preprofessionals he provision of the public welfare program services became a federal require- upon the various states who administer the categorical aid programs, as well pon their county welfare departments, if federal matching funds are to be med for administrative costs in the provision of social services to clients. lar directions in legislation were taken by Congress in the Higher Education Amendments of 1967, the Vocational Education Act of 1968, the Vocational bilitation Act Amendments of 1968, the Intergovernmental Manpower Act of 1967 - ention only some of the more noticeable pieces of legislation which have furthered career goals. There can be little question of the governmental commitment to creation of employment opportunities for the poor in public welfare. The task mplement a program of meaningful job opportunities is now a responsibility of agency. A commitment has been made to participate in this program to seek solu- s to broader social ills, while strengthening and enriching social services to e whom the agency is committed to serve.

Federal and State Regulations

In implementation of the 1967 Amendments to the Social Security Act, relating to the training and effective use of subprofessional staff as community service aides, federal regulations require each state's plan to provide for the "training and effective use of subprofessional staff as community service aides through part-time or full-time employment of persons of low income, and where applicable, of recipients...." These regulations specify five minimum requirements needed to meet the purpose intended by this legislation. These include:

"1. Such methods of recruitment and selection as will offer opportunity for full-time or part-time employment of persons of low income and low-educational achievement, including employment of young and middle-aged adults, older persons, and the physically and mentally disabled...and of recipients;

"2. an administrative staffing plan to include the range of service personnel of which subprofessional staff are an integral part;

"3. a career service plan permitting persons to enter employment at the subprofessional level and, according to their abilities, through work experience, preservice and inservice training and educational leave with pay, progress to positions of increasing responsibility and reward;

"4. an organized training program, supervision and supportive services for subprofessional staff; and

"5. annual progressive expansion of the plan to assure utilization of increasing numbers of subprofessional staff as community service aids, until an appropriate number and proportion of subprofessional staff to professional staff are achieved to make maximum use of subprofessionals in program operation."

of what their role and function will be in re

It should be noted that orientation training is consci
period of preassignment training in order to avoid arc
these new employees. Thus, by the time the Case Aide
following a one-week period of orientation training, h
understanding of his new role, the kinds of tasks he w
expectations of him as an employee, the agency progran
helping clients, and the other classifications of sta
work. The line supervisor, at this point, must help h
ning knowledge as he is given his first assignments.

. It should familiarize the new Case Aide with his rights and responsibilities as an employee as well as the beginning expectations which the agency holds for him. As such, orientation will begin a more extensive learning process which aims at helping the Case Aide to achieve identification with this new role of "employee." For many, this may involve the more difficult shift from a previous role as "client."

. It should familiarize the new Case Aide with some of the beginning tasks he will perform as a Case Aide, and the broader role to be played by the Aide, as a team member, concerned with providing meaningful services to clients. With such knowledge, the new Case Aide can begin to weigh and consider how he can draw upon his own life experiences in helping others.

. It should review major parts of the agency's program, to help the new Case Aide gain awareness of his own knowledge of public welfare and begin providing new information about portions of the program with which he is not familiar.

. It should introduce some beginning ways in which the Case Aide will work with clients, particularly on his early assignments, and provide some opportunity to practice these beginning skills.

. It should introduce the new Case Aide to some of the other classification groups of staff with whom he will be working, providing some understanding of what their role and function will be in relation to his own.

uld be noted that orientation training is consciously limited to a one-week of preassignment training in order to avoid arousing undue anxiety among new employees. Thus, by the time the Case Aide begins his job assignment, ing a one-week period of orientation training, he should have acquired some tanding of his new role, the kinds of tasks he will be performing, the agency's ations of him as an employee, the agency programs within which he will be g clients, and the other classifications of staff with whom he will jointly The line supervisor, at this point, must help him to make use of this begin- nowledge as he is given his first assignments.

'Style" of the Case Aide

bly no area dealing with the employment of Case Aides has received wider tion from professional writers than the "style" with which preprofessionals with clients, primarily because their ways of working with clients should and ffer markedly from the ways in which a social service worker will work with ts. With awareness that any discussion of style must ultimately represent alizations - as there will likely be as many exceptions to what is said as are similarities - it might still be helpful to look more closely at some of ways in which Case Aides have been characterized as working differently from social service worker counterpart on the agency team.

pproach which an Aide will take and the ways in which a Case Aide will work clients have variously been described by such words as honesty, frankness, tance, directness, informality and practicalness. In contrast to his social ce worker counterpart, the Case Aide is more likely to respond to the immedi- tated concerns and tangible needs of her client with immediate action. Dorothea ack describes this style in one of her many papers, based upon project experi- in the Alameda County Welfare Department. She says:

'Our Aides' communication with their clients is casual, friendly, and personal. They usually address each other by first names, or might easily substitute 'honey' or 'sweetie'. Aides quickly establish a common ground by mentioning their own ex-client status and openly dis- cuss their own personal experiences as mothers, homemakers, etc., to make a point. They take time to just talk to clients; even on routine contacts (i.e., picking up a completed application form) they might spend up to an hour in relaxed conversation. If they think clients might be resistant to service, they spend several visits just getting acquainted, before they move to the purpose of the referral. On the other hand, if they think the client can take it, they can be alarmingly open, direct and authoritative. They may tell a client on the first visit that she should take more baths, or keep her house cleaner. They tend to show emotions freely, expressing anger, pleasure, warmth, and affection openly."

Case Aide will most often give his prime attention to factors in the client's ernal life situation, as opposed to internal influences. Thus, it will not be ommon for a social service worker to see a client as "neglectful," while the e Aide will view this same client as "reacting to the terrible conditions in ch she lives."* Perhaps these differences in their ways of working with and ceiving of clients, which the supervisor will want to encourage, most graphically cribe why a Case Aide can be most successful in helping clients with certain kinds problems. His own economic deprivations and life experiences have provided him n coping skills which derive themselves from, and are characteristic of, the ironment from which he has come. Thus his abilities and attainments, while siderable, are more likely to be within the grasp of impoverished clients. His lities to stretch leftover food, to manage on surplus commodities, to locate gains in unusual places, and to deal with the more established institutional tems, may be highly developed - even though he is not always conscious of these lls in planning and handling his own life situation. Under such circumstances, is inevitable that the success of the Case Aide will depend in large measure n such factors as the line supervisor's ability to encourage him to further elop his own "styles" of helping; the degree to which he can be guided in ervisory instruction primarily by what is helpful to the client rather than conceived notions about how help "should be provided"; and the extent which the ervisory-worker environment can foster discovery of ways to further develop Aide's individual helping skills. Case Aides will make frequent mistakes. ever, these will not ordinarily be serious or irreparable, and if the Aide is vided the freedom to err as well as the opportunity to learn from his mistakes, gains for both the client and the Aide will be of far greater value.

ause of past life experiences, the Case Aide may also bring some attitudes and lings to this new job assignment which are dissident to the helping role he is assume. For example, because of his prior dependency upon the agency and ing to live, as a recipient, on less than adequate income, one should not be prised occasionally to find a new Case Aide coming with feelings of hostility ard and fearfulness of the agency. If recognized and planned for, both for- ized training and supervisory instruction can help the Aide to move beyond

these initial feelings in assuming his employee-helping role with clients. Dissident attitudes may be expressed in other areas as well. Several of the more common problems which have been found with the employment of Case Aides include:

1. Some Case Aides may be sensitive to what they perceive to be differential treatment of clients on the part of various social service workers. When this occurs, they may over identify with some clients, becoming hostile toward case workers who appear, to them, to be punitive in dealing with them. At such times, the Case Aide will need special supervisory help to understand his perceptions, and the effects of his reactions upon the client.

2. Some Case Aides may come to the agency with an image of "the professional" as being a person who is detached, unfeeling, and unconcerned about his clients. As with any stereotype, this may need to be repeatedly handled until the Case Aide can assume a helping role with clients which is mutually supportive with social service worker activities.

3. Some Case Aides may initially see little difference between their skills and those of the social service worker because of their belief that, having been poor, they are better able to communicate with and understand the needs of their clients. They will need help in understanding the expertise of each member of the team, and the different ways in which each can be of help to clients.

4. Some mothers who have been on AFDC may come to their Case Aide position with noticeably hostile feelings toward AFDC fathers, in general, which can, if not constructively handled, limit their ability to work with some families.

vice worker, on the other hand, is more

2. In the Case Aide's contact with clients
ably less formal. He may hug clients,
share first names.

Thus, as with any group of new staff members, characteristic kinds of problems can be identified. However, the agency skill needed is the ability to anticipate these in the planning of both formalized training as well as supervisory conferences. Attitudinal changes are an important part of any induction process whereby any new employee achieves identification with the agency's superior aims. All new employees, no matter what their classification, will come to the agency with some stereotyped attitudes, which may or may not be compatible with program goals. If new Case Aides will differ markedly from new social service workers, it is more likely to be in the way they express these attitudes, rather than the fact that they have them. The Aide will more likely present these for others to see.

In shifting from a client to an employee role, special recognition must be given to the fact that the Case Aide will be concerned about his place as an employee, and will need supervisory help in making this transition. New social service workers may complain about poor working conditions, for example, but still be able to concentrate upon the job at hand. Nevertheless, the working and environmental conditions can be of critical importance to many, including Case Aides, and for some, contribute to immobilization, if not considered in the prior planning which is done by the supervisor in anticipation of the new employee's arrival.

In summary then, the Case Aide's "style" or manner of working with clients should and will be different from that of the social service worker. In particular, these differences might best be seen in the following list of frequently observed Case Aide characteristics:

1. In his work with clients, the Case Aide frequently will provide active direction - he "decides," "announces" and "insists." (The social service worker, on the other hand, is more likely to "suggest" and "enable.")

2. In the Case Aide's contact with clients, he is more likely to be considerably less formal. He may hug clients, accept (and repay) hospitality, and share first names.

3. Mutuality of interest and shared group loyalties between the Case Aide and the client may be more evident. Thus, comments may be made to "we" blacks.

4. The Case Aide is less likely to be unencumbered by a "professional role" and thus is more likely to express himself openly and frankly.

5. The Case Aide is more likely to respond to the clients's stated need and his most visible problem.

erhaps one last problem, stemming from these characteristics, should be mentioned. This is the possibility of overidentification with the professional. t would be very easy to encourage and reward professional kinds of behavior n a Case Aide. One supervisor in a family service agency most clearly describes this skillful role which is required of the supervisor in his training f Aides.

> "I had to understand this danger and, while not discouraging the Aide's desire to 'move upward,' remember that a major goal of training is to enable them to continue to look back at how life really is in the low income community.... The supervisor must be willing to learn. We know so well that this relationship between supervisee and supervisor on any level cannot be a one-sided affair if it is to be meaningful."

hus, the "style" of the Case Aide is an important and initial part of his elping skills as well as a reflection of his life experience. Within it ill be contained the very important expertise for which the agency searches n order to enrich its program of services to clients.

he Supervision of Case Aides

mplementating a new careers concept within public welfare, will mean that the specific tasks which are to be assigned to a Case Aide, within the county epartment's program of services to clients, must make use of three essential ngredients: (1) the Case Aide's background, which is indigenous to the

15353

1. The supervisor's (and agency's) need to avoid the giving of contradictory messages to Case Aides. For example, encouraging the Aide to speak out about what he sees with other members of staff, particularly where his observations will not be welcomed.

2. The supervisor's need to make combined use of group and individual conferences, where this is possible. In the beginning of the Aide's employment, and probably for considerable time following, emphasis in his supervisory conferences should be upon asking the Aide to "tell about his interesting cases" rather than "tell about the problems he is having in his cases." Common areas of error and misconception can frequently be handled more successfully on a group, rather than an individual basis.

3. The supervisor's need to constantly and continually remind himself that he is supervising the worker, and not the individual case which which the Aide is working. Whenever possible, the Aide should be left free to accept or reject advice, providing him with the opportunity to err and to learn from his own mistakes.

s has been implied in all that has previously been said, the teaching role ich the line supervisor establishes in relation to the new Case Aide will ed to differ markedly from a more traditional academic approach. Many of ese new employees may have experienced unhappy and unsuccessful learning periences in school and prior job experiences, and thus are not as likely respond positively to this more traditional approach. For these reasons, rmalized training sessions must be planned so as to provide a more active le for the participant and, in similar fashion, teaching through supersory conference will want to place much greater emphasis upon learningrough-doing activities. Where possible, "telling" should be replaced th "showing how" and "practice" of what steps will be involved in completing particular assignment. Service activities must be broken down into simpler sks, and the time taken to assure understanding on the part of the Case Aide, each step to be involved in completing a particular task. Again, learning--doing is the primary method through which the job assignment will most ickly and thoroughly be learned.

ever ways the line supervisor finally decides to plan her super-
hing of the new Case Aide, the following factors should be reflected
hing which occurs:

aching must make maximum use of verbal communication - not reading
signments, written exercises, lectures, etc. Discussion, involving
give and take between the supervisor and the Aide(s) should emphasize
e practical steps involved in performing a task, make frequent use
illustrations and examples, and encourage the learner to draw upon
s own life experiences in seeking helping solutions.

phasis in supervisory conferences should be on specifying the par-
cular steps involved in performing an assigned task, and acquiring
e information and knowledge needed to perform the task with skill.

arning should primarily occur through active, doing activities,
llowed by discussion within which the Aide will be given the free-
m to learn from his experiences, including the mistakes he will
ke. Such teaching methods as role playing, observation and dis-
ssion appear to provide the more active learning role to be sought
the training of Aides.

formation which the Aide will need in performing his job assignment
ould be provided in simple, easily understandable terms providing
portunity to question and identify examples from his own life
perience in seeking more complete understanding.

e many questions which the Case Aide will have in the process of
arning should be responded to directly, honestly and informally,
th an opportunity for the Aide to disagree being provided.

en the Case Aide is participating in formalized training, the super-
sor will want to plan opportunity for the Aide to practice, in his
rk with clients, the use of those specific content areas taught in
ch training session.

of Adult Learning Theory in the Training of Case Aides

t that adults differ in the way they learn is a well accepted and known
most supervisors. The experienced supervisor has also learned, in his
g of adult social service workers, that even among this more homogeneous
markedly different learning patterns and styles are readily evident. Thus,
e previous discussion, it is equally evident that the Case Aide will bring
rying patterns to tax the teaching skills of the supervisor. Perhaps it
herefore, be useful to review some of the principles of adult learning which
en identified as being of particular value and use in the training of pre-
ionals. Of paramount importance to the supervisor is the need to remain
nscious of the fact that learning for this group of new employees, as with
up, requires a change in behavior. Such a change will not occur by accident.
result from a consciously planned, thoughtfully implemented, program of
g which aims at achieving clearly defined and measurable changes in behavior.

rinciples of learning appear in a variety of forms as various authors
e their experiences in training preprofessionals. Simply stated, these are:

That learning must meet a need.

That learning should be active.

3. That learning tasks and experiences should be arranged in a logical sequence, with each subsequent session building upon the preceding experience.

4. That learning should be broken down into its parts, so that the learner can comprehend the various parts which comprise the whole.

5. That learning should include repetition and sufficient opportunity to practice the skill being taught.

6. That learning should include a knowledge of results, to maximize the opportunity for learning from experiences.

7. That learning experiences must be readily recognized as being job-related by the Case Aide. In other words, he will need to see how the particular content being taught is directly related to and usable in his work with clients.

addition to these basic principles, the experiences of various county artments have clearly identified other factors which should guide the ining of Case Aides, particularly in their early months of employment. critical importance is the fact that a variety of teaching methods are e likely to achieve the results desired. Thus, formalized training ses- ns must be joined together with observational experiences and supervisory the-job training, forming a well-planned, meaningful total learning exper- ce. For this reason, learning must and should take priority in supervision in the Case Aides' early job assignments. Where this is done, these ious learning experiences will:

1. Build upon the specific knowledge and skill which each Case Aide brings to the job assignment.

2. Take advantage and utilize the Case Aide's own life experiences, and upon these build new skills needed in his job assignment.

15359 15360

3. Take advantage of the unique l
Case Aide.

CONDITIONS:

This assignment will be performed on a complete automobile

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective covers on front seat of automobile
2. Move automobile into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper manual and turn to appropiate chapter
6. Select proper tools and materials
7. Disconnect battery ground cable
8. Check manual and follow steps necessary to remove any accessories which prevent removal of generator
9. Remove battery and generator field leads from generator. (If generator has ground wire disconnect it too)
10. Remove bolt from adjusting arm
11. Remove bolts from generator bracket (those securing generator to bracket only)
12. Carefully remove fan belt and lift generator from engine compartment

PERFORMANCE CRITERIA:

1532

nds of tasks which are being assigned to Case Aides within the area
vice functions, in county departments, it is possible to identify a
three possible levels of helping techniques - a continuum of overlapping
which might be performed by the Case Aide as he develops and expands his
lls. Within such a scheme, the beginning Case Aide might help clients
by:

roviding material and concrete assistance for and with the client.

roviding information about, and help to use, resources available to
the client.

aching through action and example, ways of managing situations
ich threaten or prevent family functioning.

Aide would gain in experience and expand his helping skills, some
techniques could be taught, adding further to the ways in which he
clients. Thus, he might additionally help clients by:

ting as teacher-model (in his dealing with the client), displaying
ose kinds of behavior and methods used in solving environmental-
cial problems.

pporting positive client actions in problem solving.

the future, when further differentiation of various Case Aide levels
, and when delineation of the ways in which the social service worker
ccalaureate degree and master's degree in social work will each work
s, it is also possible to conceive of a third Case Aide level, one
, perhaps, have some overlapping functions with a beginning social
ker. Thus, the very experienced Case Aide might be taught to add
nal helping techniques to his repertoire. He would then additionally
s by:

sisting the client to perceive and appraise reality, to see alterna-
ives and to anticipate consequences through logical discussion.

15363 15364

2. Expressing his opinion and makin
decisions, where the client neec
of acting on his own.

While imperfect, this continuum of overla
to trainers by offering one way of perce
of helping,which a Case Aide might emplo
knowledge, and possibly participates in

015365

2. Expressing his opinion and making recommendations in guiding client decisions, where the client needs permission to act or is fearful of acting on his own.

While imperfect, this continuum of overlapping functions may be of some help to trainers by offering one way of perceiving of the differing levels or ways of helping,which a Case Aide might employ as he gains in agency experience and knowledge, and possibly participates in outside educational opportunities.

The "Helper Therapy Principle"

A principle of increasing interest to many social workers, is one which has been termed the "Helper Therapy Principle" - the use of people with a specific problem to help other people with a similar problem. With the addition of preprofessionals, as social service staff members within public welfare, the possible relatedness of this helper principle to the use of Case Aides, becomes more evident. Such a conscious use of people with specific problems to help others is not a new or very revolutionary idea, having already been a basic means of helping within such organizations as Alcoholics Anonymous and other similar groups. However, much of the writing on the use of such a principle has tended to focus primarily upon its potential benefit for the person being helped. In his more recent article, Frank Riessman suggests that emphasis is being placed upon the wrong person. The addition of Case Aides as members of a helping team, he believes, suggests a need to also focus our attention upon the person who is providing the help, because "frequently it is he who improves." Thus, Riessman identifies at least two important implications of the "Helper Therapy Principle" for the nonprofessional of lower socioeconomic background.

> "(1) Since many of the nonprofessionals to be recruited are former delinquents, addicts, AFDC mothers, and the like, it seems quite likely that placing them in a helping role can be rehabilitative for them. (2) As the nonprofessionals benefit from their new helping roles, they may actually become more effective workers and thus provide more help to others at a new level."

15365 15366

Carried still further, the helper principle could well pr
development of new leadership roles within agency organiz
within the culturally disadvantaged groups from which pre
Thus, one might say that "leadership can develop through

Developing and Using a Team Concept

The incorporation into the public welfare system of diffe
of social service staff (or within the separated financia
formed by the agency) raises questions around what kind o
appropriately deploy manpower in service delivery, assuri
the discovery and development of human resources within b
sons. The traditional model that the agency has used whi

15370 15367 15368 1536

ill further, the helper principle could well provide opportunity for the t of new leadership roles within agency organizations, and more importantly, culturally disadvantaged groups from which preprofessionals are recruited. might say that "leadership can develop through the process of leading," and role would provide such an opportunity to many of these persons. How can role contribute to the development of helping skills? Several mechanisms ted, including:

hat the process of advocating or persuading others about a specific osition, frequently results in a greater personal self-commitment o this same position.

hat in the process of helping, the helper is given a stake or meaning-ul part in the system. This contributes to a greater commitment to the ask, bringing about the further development of their own abilities to elp others.

conscious use of a "Helper Therapy Principle" might suggest possible wider distribution of the helper role, a potential use of it in lead-ining, and especially, as an educational tool in training preprofes-assume their Case Aide role. Certainly one could question whether a ious use of this principle has been operative already within social or many years. Who is to say that social workers themselves, along s in the helping professions, have not achieved some personal benefits helping role, much more than has generally been recognized or accepted.

and Using a Team Concept

oration into the public welfare system of different classification levels service staff (or within the separated financial assistance functions per-the agency) raises questions around what kind of agency structure can most ely deploy manpower in service delivery, assuring maximum opportunity for ery and development of human resources within both agency and client per-traditional model that the agency has used which links the client to the

15368

15369

agency via "his" caseworker must now be viewed as questionable design for the efficient and creative fulfillment of those agency goals being sought through a maximum differential use of staff. The possible face-to-face interaction between the client and a volunteer, a case aide, a social service worker, a homemaker (not to mention a similar array of possible persons within financial assistance parts of the county department), for example, requires considerable thought as to how the functions and tasks performed by each of these staff members is to be defined and organized. Unless the various activities of these persons, with an individual client, achieve some uniformity of purpose and goal, the result is all too likely to be that recently described by one client who, when asked who her worker was, responded, "I don't know, I think it's a committee."

The use of a team concept or approach suggests a different means by which agency goals might be accomplished. As implied in the use of the word "team," emphasis would be placed upon the relationship of the service giving staff to each other (or the financial assistance giving staff within their part of the county department) and to the client in the course of delivering agency program services. The social service team therefore would be composed of those staff persons engaged in face-to-face interaction with the client. Thus, while each person would have an individually assigned function (or basic job) for which he possesses a special competency, a team approach would seek to join these persons together into a mediating staff unit through which all of the program services of the agency are available to a given set of clients.

The adoption or use of such an approach must assume that the entire agency staff is directed towards the same goal of "helping" the client to cope more successfully with his life situation. Thus, in a broad sense, each staff person with whom the client will have direct interaction will be a part of an agency "work group." Within social services, they become a "social service team" that assumes responsibility with the client in a goal directed service plan. A similar team might exist within the assistance portions of the county department, and when this occurs, would comprise a part of a still larger work group of which the client is a part. What would be the common characteristic of a social service team? Five characteristics can readily be identified, including:

Robert Barker and Thomas Biggs, The Differential Use of Social Work Manpower. National Association of Social Workers, New York City, 1968.

Elliott Studt, "Fields of Social Work Practice: Organizing our Resources for More Effective Practice." Social Work, The Journal of the National Association of Social Workers, Vol. 10, No. 4 (October 1965).

1. The team members would share responsibility fo program relevant to the needs of a specific, a

2. They would comprise the primary group through responsive to individual client needs.

3. They would share commonly defined goals with e they jointly work.

4. They would be the agency in action for the cli

5. The team would be comprised of a group of spec expertise in his own right that can be brought solution of client problems.

As is readily evident in these characteristics, the mem team must share the same goal with the client. They mu cating well and collaborating in the solution of daily job to be done. Lastly, the various team members must the client in implementing a goal-directed service plan various client contacts, acceptance of the client as a

15371

1. The team members would share responsibility for making the agency program relevant to the needs of a specific, assigned group of clients.

2. They would comprise the primary group through which the agency can be responsive to individual client needs.

3. They would share commonly defined goals with each client with whom they jointly work.

4. They would be the agency in action for the client.

5. The team would be comprised of a group of specialists - each with expertise in his own right that can be brought into action in solution of client problems.

readily evident in these characteristics, the members of a social service nust share the same goal with the client. They must be capable of communi- well and collaborating in the solution of daily problems related to the be done. Lastly, the various team members must assume responsibility with lient in implementing a goal-directed service plan, and demonstrate, in their us client contacts, acceptance of the client as a person of worth and value.

y, if one is to utilize a team approach in organizing various social service functions and activities in relation to a given client, the administrative le implications for staff will be profound. For example, the supervisory n such a staff group becomes one of leadership in program adaptation, rather solely one of unilateral representation of upper authorities. An orchestration ivities of various team members becomes a necessary supervisory function. arily, a supervisor would not perform direct activities with a client, but he, ncert with the social service worker, must assure appropriate assignment of ty to other members of the team, each according to his knowledge, expertise ilities.

15371 15372

The Necessity of Providing Supportive Services

The employment of Case Aides in public welfare will
to provide some supportive services to this new emp
not clearly defined within the county department fo
vices. Certainly, it is important to recognize tha
to this new job assignment with personal and family
their ability to assume this new helping role. Car
or compound these problems in the employment settin
assist the Aide in overcoming these problems which
his performance of assigned tasks.

Thus, it will be necessary for supportive help to b
ing groups as well as individual supervisory confer
tation and induction, the mutual aid system establi
has been used effectively in some county department
initial anxieties, problems with role change, and i
outside or personal influences which impinge upon t
employee role. For example, one Case Aide whose to
been in domestic work, initially had much difficult
did not pay her transportation to and from work - a
previous employment. The group could, in several m
her to see that employment in this setting does not
the responsibilities which she must assume in under
member. In addition to expected difficulties in ro
problems may require the supervisor's help, either
where brief or short-term help can eliminate a more
referral to a resource who can assist the Aide with
problems as day care for children, illness of a fam
parent-child discord, etc., may each find their way

ABSTRACT - This 2-part training guide was prepared for teachers by the Training Bureau of the Human Relations Agency, California State Department of Welfare, and outlines major areas of content necessary to adequately prepare case aides to perform job duties. The 88-hour training program consists of a 1-week orientation period (40 hours) of planned group instruction and observational experiences, which is followed by a 1 to 3-month induction training period (48 hours) of planned group instruction in combination with supervised on-the-job training. Part 1 provides a series of 17 orientation training sessions and accompanying lesson plans, references, and suggested content and teaching methods, and Part II provides 23 induction training sessions organized in a similar manner. Both parts are preceded by an outline of the sessions and a brief description of the content in each session. An annotated bibliography and an exercise in team training are appended. A related workbook is available as VT 012 918 also in this issue. (SB)

INTRODUCTION

A recent manpower innovation within the human services has been the devel careers concept" and its resulting movement towards an expanded use of pr team members, in the provision of services to clients. The Scheurer Amen Opportunity Act, in 1966, provided initial commitment of the federal gove through the establishment of New Careers Programs, whose purpose was to d programs for persons from poverty areas, to prepare them for new employme created. The 1967 Amendments to the Social Security Act moved further to career concept" within public welfare itself. This legislation required ment and use of preprofessionals in the provision of public welfare servi

The implementation of a "new careers concept" within public welfare has f of two program goals. The first reflects a desire to expand and enrich s clients, by expanding the agency's use of different classification levels reflects the agency's desire to provide meaningful job opportunities for previously denied access to public welfare employment because of educatio a result of this legislation and its incorporation into federal regulatio ments have already moved to employ Case Aides to perform tasks within b and social service programs. This training aid has been developed in res of this new personnel classification. It is intended for use by county w their orientation and induction training of new Case Aides.

The addition of Case Aides, as members of an agency team, requires admini preparation, of which training comprises one very important part. It is orientation and induction training of these new staff members will build administrative planning:

1. A clear identification of the tasks, roles and responsibilities levels of staff within the county department.

2. An understanding on the part of all employees of the role and r Case Aide and his relationship to the Social Service Worker, th and other classifications of staff with whom he will be working

3. A differentiation of the training responsibilities to be assign members, and a clear understanding of the role of each of these teaching the Case Aide.

15390

ower innovation within the human services has been the development of a "new
ot" and its resulting movement towards an expanded use of preprofessional staff, as
in the provision of services to clients. The Scheurer Amendment to the Economic
ct, in 1966, provided initial commitment of the federal government to this concept
stablishment of New Careers Programs, whose purpose was to develop educational
persons from poverty areas, to prepare them for new employment opportunities being
1967 Amendments to the Social Security Act moved further to incorporate the "new
t" within public welfare itself. This legislation required the training, employ-
of preprofessionals in the provision of public welfare services to clients.

ation of a "new careers concept" within public welfare has focused upon achievement
n goals. The first reflects a desire to expand and enrich social services to
xpanding the agency's use of different classification levels of staff. The second
agency's desire to provide meaningful job opportunities for welfare recipients,
nied access to public welfare employment because of educational requirements. As
his legislation and its incorporation into federal regulations, many county depart-
ready moved to employ Case Aides to perform tasks within both income maintenance
rvice programs. This training aid has been developed in response to the creation
ersonnel classification. It is intended for use by county welfare departments in
tion and induction training of new Case Aides.

of Case Aides, as members of an agency team, requires administrative planning and
of which training comprises one very important part. It is assumed that the
nd induction training of these new staff members will build upon the following
e planning:

lear identification of the tasks, roles and responsibilities of various classified
els of staff within the county department.

understanding on the part of all employees of the role and responsibilities of the
e Aide and his relationship to the Social Service Worker, the Eligibility Worker
other classifications of staff with whom he will be working.

ifferentiation of the training responsibilities to be assigned to selected staff
bers, and a clear understanding of the role of each of these staff members in
ching the Case Aide.

15390 12339 SESSI

From the various job specifications for Case Aides, developed
can identify a number of tasks more commonly used in these sta
for this training aid. These tasks are grouped under four are
function:

1. Direct Service Functions:

   a. Shows, demonstrates and advises clients on such
      buying, household management, budget planning

   b. Briefly cares for children so that a mother ca
      first days at school, clinic appointment, etc.

   c. Locates and escorts client through the use of
      resource.

   d. Talks with client to identify material needs (
      suitable laundry facilities, etc.) hampering a
      effective home management.

   e. Suggests the cooperation and joining together
      and advises group in planning cooperative proj
      problems (i.e., the pooling of transportation
      appointments, the sharing of babysitting servi

   f. Visits isolated clients to ask if material nee

2. Joint Functions:

   a. Secures specific information from clients need
      eligibility for financial assistance.

   b. Escorts hesitant client to, from and through t
      resource.

   c. Demonstrates how to secure and assist client t
      suitable housing, the location of some special

   d. Surveys the receptiveness and possible use of
      summer camps for children).

15392

job specifications for Case Aides, developed by county welfare departments, one mber of tasks more commonly used in these statements and which serve as a basis aid. These tasks are grouped under four areas descriptive of their major

Service Functions:

ows, demonstrates and advises clients on such matters as food preparation and ying, household management, budget planning and child rearing.

iefly cares for children so that a mother can accompany a fearful child to his rst days at school, clinic appointment, etc.

cates and escorts client through the use of a neighborhood and/or community source.

lks with client to identify material needs (repair of stove, location of more itable laundry facilities, etc.) hampering achievement of more efficient or fective home management.

ggests the cooperation and joining together of a group of individual clients, d advises group in planning cooperative projects towards solution of common oblems (i.e., the pooling of transportation resources to maintain clinic pointments, the sharing of babysitting services, etc.).

sits isolated clients to ask if material needs are being met.

Functions:

ecures specific information from clients needed in determining or redetermining ligibility for financial assistance.

scorts hesitant client to, from and through the use of a specific community esource.

emonstrates how to secure and assist client through the process of locating ultable housing, the location of some special need item, etc.

urveys the receptiveness and possible use of special programs by clients (i.e., ummer camps for children).

e. Shows clients how to complete selected forms.

3. Bridging Functions:

a. Explains and advises clients (or groups of clients) on the use o in the county department.

b. Gathers specific information from neighborhood people or groups, door canvassing, etc.

c. Visits and talks with school personnel, community agency staff n secure specific information needed.

d. Locates and meets with established neighborhood groups which hav improvement goals, to provide information about the agency.

4. Recruitment and Follow-up Functions:

a. Asks client questions to determine why he has been unable to fol contacting or using a specific resource.

b. Asks client questions to determine why agency appointment was no

c. Advises and assists client in making initial request for agency for special need items, etc.

To the various tasks listed above, each county welfare department has identifie unique to the specific needs and programs of the county, which should be added the administrative planning of orientation and induction training for Case Aide

The Purpose of the Training Aid

The purpose of this training aide is to provide, in outline form, major areas o necessary to adequately prepare Case Aides to perform those tasks more commonly classifications of staff; to suggest methods of teaching this content; and to o where additional information can be secured. To this, the county department wi additional content relating to those more unique tasks which have not been list which take advantage of the specific background and skills of an individual aid

ws clients how to complete selected forms.

Functions:

ains and advises clients (or groups of clients) on the use of resources with-
he county department.

ers specific information from neighborhood people or groups, does door-to-
canvassing, etc.

ts and talks with school personnel, community agency staff members, etc., to
re specific information needed.

tes and meets with established neighborhood groups which have neighborhood
ovement goals, to provide information about the agency.

nt and Follow-up Functions:

client questions to determine why he has been unable to follow through in
acting or using a specific resource.

client questions to determine why agency appointment was not kept.

ses and assists client in making initial request for agency social services,
special need items, etc.

s listed above, each county welfare department has identified other tasks, more
fic needs and programs of the county, which should be added to the list in
planning of orientation and induction training for Case Aides.

Training Aid

training aide is to provide, in outline form, major areas of content
tely prepare Case Aides to perform those tasks more commonly assigned to such
staff; to suggest methods of teaching this content; and to offer references
formation can be secured. To this, the county department will want to add
relating to those more unique tasks which have not been listed above and/or
e of the specific background and skills of an individual aide.

15395

The Training Model Used

The experiences of county departments to date has shown that spe the methods and techniques used in training Case Aides, as they learn from many of the adults upon whom county department have p training time. For example, the Case Aide is more likely to hav or experience which was limited to the assignment of specific ro as each was performed. Thus, he may not have developed a way of application of more generalized material to a variety of assigne explicit instruction and guidance, particularly in the early mon county department.

A number of general principles can be identified which should gu Case Aides, and which have influenced the specific model of orie used in this training aid. These include:

1. Group training and initial on-the-job training assign edge and skills which the Case Aide brings to his new

2. Training will be most effective where planned group t supervisory conferences build upon experience-based d and concepts are introduced at appropriate points wit examples.

3. Orientation and induction training must provide oppor cuss and prepare for a shift in roles, in some cases of employee.

4. Training must take advantage of the learning patterns In doing so, it will provide opportunities to learn b ing methods (discussion, role playing, etc.) which st can be seen and experienced concretely.

The model proposed in this training aid provides for a brief on the agency, comprising forty hours of preassigned training, whi planned observational experiences. The purpose of this period familiarize the Case Aide with agency organization and operatio training will provide knowledge of the background, basic philos and the opportunity to develop enough basic skills to begin wor immediately followed by a one- to three-month period of inducti hours of planned group [illegible]on, in combination with supervi

red in this training aid have been selected because they represent the
tly identified tasks listed in county welfare department class specifica-
developed and used in hiring Case Aides and related pre-professional
ecause of this, individual county departments may find that, because of
which they assign to this classification of employee, a specific content
uded or that one which is included may or may not be appropriate. In
department will want to modify the overall plan to include specific
the specific needs of their Case Aides. In any event, such changes and
reduce the overall period of training needed by these new employees.

ation of the Training Aid

sts of two major parts and an appendix of supplemental information.
ries of seventeen orientation training sessions, organized in three
e" column lists books and articles of use to the trainer in his prepara-
training session. The center column contains teaching outlines or
the main points to be covered in each session. The column headed
offers information about the content and suggests teaching methods for

eries of twenty-three induction training sessions organized in the same
tion. Both are preceded by an outline of the sessions and a brief
ent to be covered in each session. An appendix to the training aid con-
iography of selected materials on the training, employment and use of
human services; as well as an exercise in team training, for use in
ion number eighteen.

A second training aid, 38B, A Workbook for Case Aides in Orienta been developed for use by the trainee participating in these ori sessions. This aid contains a series of "learning by doing" exe ments for use by the Case Aide in relation to individual trainir a place for the participant to keep class notes is provided.

Suggestions for Use of The Training Aid

The training of Case Aides may, in some county departments, be staff members and demands upon staff time may be eased through lesson plan briefly outlines the content to be taught and empha be covered by the instructor. However, in using this material, ment, broaden and expand this basic outline, making those modif necessary to assure that each session is relevant to the learni participating in training, and to the specific tasks which they department. It is not important that all of the points outline covered in the training session. What is important is that the presented in a tangible and useable manner. Teaching should ma assumptions explicit, and concepts which are introduced should practical use in work with clients. The Case Aides own life ex for group discussion as well as the introduction of new content discussion should be a primary method of instruction. Wherever responsibility should be assigned to a single person who can pr orientation and induction training, although other persons may group for specific instructional purposes.

Particularly during the period of orientation training, the tra questions and anxieties which these new Case Aides bring, and, developed prior to their arrival, it is important that the con guided by the learning needs of the specific aides in training cover the content he has planned in this week period, but he i reordering parts of the material to the readiness of his group his new assignment, the Case Aide must first see himself as an an agency team. Identification with this new role of "employe the agency are therefore important elements of orientation tra

Because this plan combines planned group sessions with observa training, the planning of these latter experiences become an i process. Care must be exercised in selecting the employee who

, 38B, A Workbook for Case Aides in Orientation and Induction Training, has
e by the trainee participating in these orientation and induction training
ontains a series of "learning by doing" exercises and brief reading assign-
Case Aide in relation to individual training sessions planned. In addition,
cipant to keep class notes is provided.

f The Training Aid

Aides may, in some county departments, be the responsibility of a number of
ands upon staff time may be eased through use of this training aid. Each
utlines the content to be taught and emphasizes the most important points to
tructor. However, in using this material, the teacher will want to supple-
and this basic outline, making those modifications in content which are
hat each session is relevant to the learning needs of Case Aides who are
ning, and to the specific tasks which they will be performing in the county
t important that all of the points outlined in a specific lesson plan be
ng session. What is important is that the major concepts and principles be
le and useable manner. Teaching should make use of many illustrations, make
and concepts which are introduced should be explicitly related to their
with clients. The Case Aides own life experiences should serve as a basis
as well as the introduction of new content. For this reason, small group
a primary method of instruction. Wherever possible, primary training
be assigned to a single person who can provide continuity throughout
tion training, although other persons may be asked to join the teaching
structional purposes.

he period of orientation training, the trainer should focus upon the many
es which these new Case Aides bring, and, although a plan is proposed and
eir arrival, it is important that the content and sequence be adapted and
g needs of the specific aides in training. Thus, the skillful teacher may
has planned in this week period, but he is equally capable of changing and
he material to the readiness of his group. Before being able to undertake
he Case Aide must first see himself as an agency employee and as a member of
tification with this new role of "employee" and with the superior aims of
fore important elements of orientation training.

mbines planned group sessions with observational experiences in orientation
g of these latter experiences become an important part of the total learning
e exercised in selecting the employee who will provide this experience and,

ideally, the person will, in his work with clients, express the q
person. In most of the observations planned, an experienced Case
model to provide this early learning experience, although a Socia
(where a Case Aide is not available) if the differences in his wa
Case Aide, is clearly differentiated and the service functions he
in part, to the kinds of tasks the Case Aide will be performing.
the fact that the Case Aide will be fulfilling a defined role in t
of this role in achieving agency program objectives.

Induction Training combines the use of formalized group training s
ing. For maximum effectiveness, the activities of the trainer, wh
sessions each week, must be coordinated with on-the-job training n
supervisor, if the Case Aide is to be provided with opportunity to
provided in group sessions.

During the first three months of employment, the tasks assigned by
selected on the basis of learning needs. Thus, they should:

1. Be within the capacity of the Case Aide; physically, emo

2. Provide an opportunity to practice what is being taught i
sessions;

3. Provide an opportunity to learn one new task at a time an

4. Early assignments should involve the provision of concret

the Case Aide will be fulfilling a defined role in the agency, and the importance
in achieving agency program objectives.

ining combines the use of formalized group training sessions with on-the-job train-
imum effectiveness, the activities of the trainer, who plans and conducts group
week, must be coordinated with on-the-job training now being provided by the line
f the Case Aide is to be provided with opportunity to use the content being
roup sessions.

rst three months of employment, the tasks assigned by the line supervisor should be
he basis of learning needs. Thus, they should:

within the capacity of the Case Aide; physically, emotionally, and educationally;

vide an opportunity to practice what is being taught in his weekly group training
sions;

vide an opportunity to learn one new task at a time and in a sequential manner;

ly assignments should involve the provision of concrete kinds of services, which can
provided by the Case Aide in one or two client contacts. Later, when sufficient
cess has been achieved in this type of activity, services involving a series of con-
ts can be introduced.

d group training sessions planned during the introduction period should be scheduled
s each week in either one block period of time, or in two, two-hour sessions. These
to be oriented towards meeting the educational needs of the Case Aide as he
is job assignment. Because the content of these sessions was developed from common
nts for beginning Case Aides, identified by county departments, the trainer may want
e sequences of specific sessions, depending upon the specific county plan for the
ides. Following each group session, an opportunity to use this content on his job
to be planned by the line supervisor, and coordination of this planning should be a
of the trainer.

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: VI. ALTERNATOR

PERFORMANCE OBJECTIVE NO.: 6 TITLE: Remove, Disassemble, Reassemble, Replace, and Test Alternator

CONDITIONS:

This assignment is to be performed on a complete automobile

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective covers on front seat of automobile
2. Move automobile into proper work station
3. Raise hood
4. Place protective covers on fenders
5. Select proper manual and turn to appropiate chapter
6. Select proper tools and materials
7. Disconnect the battery ground cable
8. Check manual and follow steps as outlined to remove any accessories which prevent removal of alternator
9. Remove Alternator battery and alternator field leads from alternator - If alternator has ground wire, disconnect it
10. Remove bolt from adjusting arm
11. Remove bolts from alternator bracket (those bolts securing alternator to bracket)

PERFORMANCE CRITERIA:

The Purpose of Orientation Training

The purpose of orientation training sessions essentially is on
to the agency and his job assignment. As such, it should unde
agency organization and operation and provide him with the nec
the agency, including the basic philosophy and purposes for wh
orientation training should provide an opportunity for the new
skills in order to begin his specific job assignment.

In order to achieve the above, the orientation sessions in thi
broad areas of content including:

1. What are the rights, responsibilities and expectatio
welfare department employee?

2. What tasks will he be performing as a Case Aide?

3. What are the agency programs within which he will be

4. How will he work with clients?

5. What other classifications of staff will he be worki

Certainly, it will not be possible to cover these five content
of orientation training. However, by the end of this orientat
acquired a perception of his new role of "employee" and an und
as a Case Aide within the county welfare department.

An Outline of Orientation Sessions

Session 1 - INTRODUCTION AND ORIENTATION TO TRAINING PROGRA

An informal group session designed to introduce
gram, to review the learning experiences planne
and to begin an establishment of a sense of "we
cussion of employee rules and regulations are a
beginning session.

15407

pose of Orientation Training

pose of orientation training sessions essentially is one of introducing the new Case Aide agency and his job assignment. As such, it should undertake to familiarize him with the organization and operation and provide him with the necessary background information about ncy, including the basic philosophy and purposes for which the agency exists. In addition, tion training should provide an opportunity for the new Case Aide to develop enough basic in order to begin his specific job assignment.

to achieve the above, the orientation sessions in this training aid seek to cover five reas of content including:

What are the rights, responsibilities and expectations of the Case Aide as the county welfare department employee?

What tasks will he be performing as a Case Aide?

What are the agency programs within which he will be performing Case Aide tasks?

How will he work with clients?

What other classifications of staff will he be working with?

ly, it will not be possible to cover these five content areas totally during this one week ntation training. However, by the end of this orientation training period, he should have d a perception of his new role of "employee" and an understanding of how he will function se Aide within the county welfare department.

ine of Orientation Sessions

1 - INTRODUCTION AND ORIENTATION TO TRAINING PROGRAM - 2 hours

An informal group session designed to introduce the Case Aides to the training program, to review the learning experiences planned, the objectives to be achieved, and to begin an establishment of a sense of "we-ness" among participants. A discussion of employee rules and regulations are also an important part of this beginning session.

Session 2 - A TOUR OF COUNTY DEPARTMENT, INTRODUCTIONS, ETC. - 2 hours

A tour of the county department to physically orient the new
ting they will be working in and to introduce them to key pe
will later be working.

Session 3 - WHAT DO CASE AIDE'S DO? - 2 hours

A discussion of the need for Case Aides in public welfare,
appropriate case aide tasks and functions and appreciation
be made by aides in achieving agency goals.

Session 4 - OBSERVATIONAL EXPERIENCE - 2 hours

An individual observation, preferably with an experienced C
basis for participants to expand and clarify their percepti
Case Aide, and to compare the various helping tasks which t
prior conceptions of this role.

Session 5 - WHAT IS PUBLIC WELFARE?- 2 hours

Beginning with participant perceptions, the purpose and obj
welfare programs are discussed, with emphasis upon categori
with whom case aides will initially be working.

Session 6 - A DISCUSSION OF VARIOUS PUBLIC WELFARE PROGRAMS, SERVICES,

The reasons why services are provided in addition to assist
and the kinds of service resources available in the agency
prior use of these services by participants can contribute
cussion to consideration of ways to help clients make maxim

Session 7 - OBSERVATIONAL EXPERIENCE - 4 hours

An individual observational experience where interpretation
service or resource, or an information service is provided,
aide with an example of how one can interpret the use of a

AIDE'S DO? - 2 hours

of the need for Case Aides in public welfare, identification of
ase aide tasks and functions and appreciation of the contribution to
des in achieving agency goals.

EXPERIENCE - 2 hours

observation, preferably with an experienced Case Aide, will provide a
ticipants to expand and clarify their perceptions of the role of a
d to compare the various helping tasks which they have observed with
ions of this role.

C WELFARE?- 2 hours

h participant perceptions, the purpose and objectives of public
ams are discussed, with emphasis upon categorical programs of clients
e aides will initially be working.

OF VARIOUS PUBLIC WELFARE PROGRAMS, SERVICES, AND RESOURCES - 2 hours

hy services are provided in addition to assistance will be reviewed,
of service resources available in the agency discussed. The possible
these services by participants can contribute to expansion of the dis-
nsideration of ways to help clients make maximum use of such resources.

EXPERIENCE - 4 hours

observational experience where interpretation of a public welfare
esource, or an information service is provided, will provide the case
example of how one can interpret the use of a resource to a client.

Session 8 - THE QUALITIES OF A HELPING PERSON - 2 hours

Identification of these factors which will create confidence in the
the part of clients, and a discussion of the importance of understan

Session 9 - HOW DOES A CASE AIDE HELP? - 2 hours

The characteristic ways of helping, use by Case Aides, are discussed
ways of establishing rapport, preparing for an interview, hints on i
and ending the interview.

Session 10 - OBSERVATIONAL EXPERIENCE - 4 hours

An individual observation is provided for each Case Aide, preferably
ienced aide providing a service to a client. The Case Aide can iden
and characteristics utilized by the helping person for comparison, i
with previously identified qualities and characteristics in Sessions

Session 11 - THE PUBLIC WELFARE TEAM - 2 hours

The public welfare team is defined, its characteristics identified a
and functions of the various agency employees who comprise the team
in this session.

Session 12 - CASE PRESENTATION AND DISCUSSION - 2 hours

A case presentation by an Eligibility Worker and Social Service Work
with emphasis upon their differing roles and responsibilities with t
serve as a basis for discussing the ways in which the case aide will
a member of a team, in helping the client.

Session 13 - OBSERVATIONAL EXPERIENCE - 4 hours

An observational experience of an Eligibility Worker and/or Social S
will provide opportunity for the participant to further clarify his
entiate this from those roles of other team members.

OF A HELPING PERSON - 2 hours

n of these factors which will create confidence in the Case Aide, on lients, and a discussion of the importance of understanding others.

SE AIDE HELP? - 2 hours

istic ways of helping, use by Case Aides, are discussed, including: lishing rapport, preparing for an interview, hints on interviewing, e interview.

EXPERIENCE - 4 hours

observation is provided for each Case Aide, preferably of an exper- roviding a service to a client. The Case Aide can identify qualities stics utilized by the helping person for comparison, in discussion, y identified qualities and characteristics in Sessions 8 and 9.

LFARE TEAM - 2 hours

fare team is defined, its characteristics identified and the (roles) of the various agency employees who comprise the team are discussed on.

TION AND DISCUSSION - 2 hours

cation by an Eligibility Worker and Social Service Worker is planned, upon their differing roles and responsibilities with the client, to sis for discussing the ways in which the case aide will contribute, as team, in helping the client.

EXPERIENCE - 4 hours

nal experience of an Eligibility Worker and/or Social Service Worker opportunity for the participant to further clarify his role and differ- from those roles of other team members.

15412

Session 14 - SOME CONCEPTS USED IN THE HELPING SERVICES - 2 hours

Selected concepts of social work practice - confidentiali
dignity and worth of the individual, rights and responsib
presented and discussed in terms of Case Aide functions.

Session 15 - EXPECTATIONS AND RESPONSIBILITIES - 2 hours

A review of expectations, rights and responsibilities of
personnel policies affecting employees and future trainin
encourage the Case Aide's continued development is planne

Session 16 - REVIEW OF WEEKS ACTIVITIES AND GROUP EVALUATION - 2 hours

A review of the week orientation, content areas covered,
ples discussed, and a discussion of these experiences in
has occurred.

Session 17 - A MEETING WITH INDIVIDUAL SUPERVISORS - 2 hours

A brief conference between the Case Aide and his ongoing
which the purpose of supervision can be briefly introduce
for introduction to persons he will be working with, wher
following Monday, and the location of his desk can be cov

SOME CONCEPTS USED IN THE HELPING SERVICES - 2 hours

Selected concepts of social work practice - confidentiality, self-determination, the dignity and worth of the individual, rights and responsibilities of clients - are presented and discussed in terms of Case Aide functions.

EXPECTATIONS AND RESPONSIBILITIES - 2 hours

A review of expectations, rights and responsibilities of all public welfare employees, personnel policies affecting employees and future training programs designed to encourage the Case Aide's continued development is planned.

REVIEW OF WEEKS ACTIVITIES AND GROUP EVALUATION - 2 hours

A review of the week orientation, content areas covered, major concepts and principles discussed, and a discussion of these experiences in terms of learning which has occurred.

A MEETING WITH INDIVIDUAL SUPERVISORS - 2 hours

A brief conference between the Case Aide and his ongoing supervisor is planned, in which the purpose of supervision can be briefly introduced; and ample time exists for introduction to persons he will be working with, where he is to report on the following Monday, and the location of his desk can be covered.

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: VI. ALTERNATOR

PERFORMANCE OBJECTIVE NO.: 6 TITLE: Remove, Disassemble, Reassemble, Replace, and Test Alternator

CONDITIONS:

BEHAVIOR:

12. Carefully remove fan belt and lift alternator from engine compartment
13. Disassemble alternator following steps as outlined in manual
14. Make all tests and checks as outlined in manual
15. Reassemble alternator following steps as outlined in manual
16. Make all final bench checks as outlined in manual
17. If all final tests and checks are satisfactory, proceed as follows;
18. Return alternator to engine compartment
19. Bolt alternator to bracket but do not tighten
20. Put fan belt on alternator (check condition of fan belt and replace if necessary)
21. Bolt alternator to adjusting arm
22. With proper tool, move out on alternator until proper belt tension is obtained
23. Tighten alternator adjusting bolts and alternator to engine bracket bolts

PERFORMANCE CRITERIA:

1537

f. How you will work with the Social Serv and Eligibility Worker.

g. County department rules and procedures followed by all employees.

D. Content

1. Outline of content.

2. Training schedule.

3. Employee rules and procedures.

E. Distribution of the Workbook

15416

15417

1. Introduction and Orientation Session	Comments, Suggestions
f. How you will work with the Social Service and Eligibility Worker. g. County department rules and procedures followed by all employees. Content 1. Outline of content. 2. Training schedule. 3. Employee rules and procedures. Distribution of the Workbook	C. If the workbook schedule is not used, a schedule should be reproduced and discussed in detail to be sure that each participant understands where he is to be and with whom. Employee rules and procedures discussed at this time should be limited to beginning essentials. (i.e., working hours, coffee breaks, where employees park their automobiles, etc.) If the workbook is to be used by the trainer, it can be distributed and its purpose briefly explained. Time to read the introduction should be provided and its use for note taking reviewed. Confidentiality, which is covered in Session 14, may need to be included earlier in some county departments.

15418

15417

A. Objective

To identify and locate significant persons with
he will be working, and employee-related facilit
which he will be using.

B. Content to be covered.

1. The physical relationship of various office
each other.

2. Meeting significant persons with whom the C
Aide will later be working, including:

a. His supervisor.

b. His department or division head.

c. Other persons in the unit to which he
assigned.

3. Employee-related facilities.

a. The door which employees use.

b. The restroom and lunch facilities.

c. Where employees hang their coats, keep
purses, etc.

d. Where employees park their cars.

e. How employees sign in or out, who they
obtain materials, and what supplies are
available for them.

15419

2. A Tour of County Department

Comments, Methods

A. Objective

To identify and locate significant persons with whom he will be working, and employee-related facilities which he will be using.

B. Content to be covered.

1. The physical relationship of various offices to each other.

2. Meeting significant persons with whom the Case Aide will later be working, including:

   a. His supervisor.

   b. His department or division head.

   c. Other persons in the unit to which he will be assigned.

3. Employee-related facilities.

   a. The door which employees use.

   b. The restroom and lunch facilities.

   c. Where employees hang their coats, keep their purses, etc.

   d. Where employees park their cars.

   e. How employees sign in or out, who they see to obtain materials, and what supplies are available for them.

The tour of the county department office is for the purpose of orienting the participants to the physical environment in which they will be working. Special attention should be given to:

1. Meeting the immediate supervisor with whom the participant will later be working, as well as other significant people.

2. Locating where and with whom he will be working.

3. Identifying facilities used by employees.

Emphasis upon their employee status and what employees do is important.

Ask participants to complete their workbook assignment on page 4, for the next session. Class time may need to be allowed for this.

15420

3. What do Case Aides do?	Comments, Suggestions
<u>Objective</u> To identify some of the major tasks he will be performing as a Case Aide. <u>The Need For Case Aides in Public Welfare</u> 1. The need to enrich social services to clients. 2. Many tasks can be performed by a Case Aide. 3. Better utilization of the skills of all staff. 4. More jobs are made available for persons in the helping services. 5. The need to provide career development opportunities for all staff members.	This session can begin with a discussion of the workbook assignment on page 4, and a review of the questions listed in relation to this example.
<u>Examples of Case Aide Functions and Tasks</u> 1. Direct Service Functions, such as: a. Advised clients on food preparation and buying. b. Demonstrates for clients how to purchase food more carefully. 2. Joint Functions, such as: a. Shows client how to complete a specific form. b. Escorts hesitant client to and through a family planning clinic.	Participants should be encouraged to draw upon their own experiences in identifying possible Case Aide tasks under each category. Use a blackboard to list tasks, adapting participant suggestions and filling in areas which are omitted. The trainer will want to modify examples to be compatable with specific tasks being assigned to aides in the county department.

3. Bridging Functions, such as:

   a. Advises clients on the use of a resource w in the county department.

   b. Gathers specific information on a neighbor through door-to-door canvassing.

4. Recruitment and Follow-up Functions, such as:

   a. Asking a client why he was unable to follo through in contacting or using a specific resource.

   b. Assisting a client to make a request for agency social services.

D. The Contribution to be Made by the Case Aide

1. The Case Aide has an important contribution to make in planning for agency clients.

2. The Case Aide comes with special knowledge and client experience that can ease his communicat with and appreciation of clients with whom he work.

3. The Case Aide can serve as a liaison between t client with whom he works, and the agency whic he represents.

4. The Case Aide can offer interpretation of clie and neighborhood behavior.

5. The Case Aide can offer some special and uniqu services to clients.

New Careers: The Community/Home Health Aide Trainers Manual. National Institute of New Careers, University Research Corporation. Washington, D. C., October 1968.

15423

154

3. What do Case Aides do?	Comments, Suggestions
3. Bridging Functions, such as:	
a. Advises clients on the use of a resource within the county department.	
b. Gathers specific information on a neighborhood through door-to-door canvassing.	
4. Recruitment and Follow-up Functions, such as:	
a. Asking a client why he was unable to follow through in contacting or using a specific resource.	Case Aides should be encouraged to identify specific skills and experiences they have had which they feel now are helpful to a client.
b. Assisting a client to make a request for agency social services.	
D. <u>The Contribution to be Made by the Case Aide</u>	
1. The Case Aide has an important contribution to make in planning for agency clients.	
2. The Case Aide comes with special knowledge and client experience that can ease his communication with and appreciation of clients with whom he will work.	
3. The Case Aide can serve as a liaison between the client with whom he works, and the agency which he represents.	
4. The Case Aide can offer interpretation of client and neighborhood behavior.

4. Observational Experience

A. Objective

To identify and describe in detail one way in which Case Aide helped a particular client.

B. Suggested Guidelines for Planning the Observational Experience

The purpose of this first observational experience is to provide the learner with an opportunity to observe an experienced Case Aide performing an appropriate agency helping function with a client.

1. The function should be representative of one earlier considered in group discussion.

2. The tasks performed should be relatively simple ones, similar to the kind a new Case Aide will b assigned in the coming weeks.

3. The Case Aide should be told something about the observational experience, including:

   a. Information about the family they will be visiting.

   b. The problem with which the aide is planning to help the family.

   c. What he plans to do.

   d. How she and the client were brought togeth (how the referral of this family came to h

   e. What he will do with any additional inform tion he obtains at the visit.

15425

15426

4. Observational Experience

Comments, Suggestions

A. <u>Objective</u>

To identify and describe in detail one way in which a Case Aide helped a particular client.

B. <u>Suggested Guidelines for Planning the Observational Experience</u>

The purpose of this first observational experience is to provide the learner with an opportunity to observe an experienced Case Aide performing an appropriate agency helping function with a client.

1. The function should be representative of one earlier considered in group discussion.

2. The tasks performed should be relatively simple ones, similar to the kind a new Case Aide will be assigned in the coming weeks.

3. The Case Aide should be told something about the observational experience, including:

   a. Information about the family they will be visiting.

   b. The problem with which the aide is planning to help the family.

   c. What he plans to do.

   d. How she and the client were brought together (how the referral of this family came to him).

   e. What he will do with any additional information he obtains at the visit.

A social service worker may be used where an experienced Case Aide is not available, but care must be taken to distinquish between Case Aid and Social Service tasks performed.

Ask participants to complete their workbook assignment, following their observation, on page 6.

Opportunity for participants to discuss this observational experiences in the learning group should be planned immediately following the experience, or at the next planned group session.

Ask participants to complete the workbook assignment on page 7, in preparation for the next session.

5. What is Public Welfare?

Comments, Suggestions

A. <u>Objective</u>

To identify and discuss the three broad purposes of public welfare, and differentiate between the various categorical aid programs through which financial assistance is provide to clients.

(Some Trainers may prefer to schedule sessions 5 and 6 prior to session 3.)

B. <u>The Purpose of Public Welfare</u>

Public Welfare Seeks to:

1. Support and maintain financially needy persons <u>by</u>
   a. Providing money and/or vendor payments
   b. Certification of eligibility

   <u>through</u>

   a. Categorical Aid programs
   b. General Assistance program
   c. Food Stamp program
   d. Medi-Cal program

   <u>In order to</u>

   Enable financially needy people to subsist at a level compatible with health and decency when, despite their best efforts, they cannot support themselves.

2. Conserve the human resources of people

   <u>by</u>

Discussion will draw upon the perceptions of Public Welfare which participants bring to their new job assignment. Summarize the case example in the workbook on page 7 and discuss the questions which Case Aides answered in completing this assignment.

These purposes can be graphically represented on a blackboard to serve as a basic model of Public Welfare upon which later discussion can build.

Participants should develop a list of examples for each of these broad program areas.

Comments, Suggestions

to

a. Provide assurance to the public that agencies and facilities serving children and adults meet appropriate standards.

b. Protect the public against irregular child placement practices.

The Categorical Aid Programs

1. Old Age Security (OAS)

   For persons 65 years of age or older.

2. Aid to Families with Dependent Children (AFDC and AFDC-U)

   a. Aid to dependent children who are in need and lack parental support and care because of death, continued absence from the home, and incapacity of one or both parents.

   b. Aid to children whose need stems from the unemployment of the father, or under limited circumstances, the mother.

3. Aid to the Blind (AB) and Aid to the Potentially Self-Supporting Blind (APSB)

   a. A minimum age of 16 years

   b. A definition of economic blindness (1/10th of normal eyesight or less)

The brochure Public Assistance and Welfare Services in California can serve as reading and reference material for participants.

The purpose of this overview is not to teach detailed eligibility requirements for these various programs. Instead, emphases should be on providing sufficient information to assure an awareness of potential agency resources.

Emphasis and more detailed information will need to be included on those categorical aid programs with which the case aide may be working.

4. Aid to the Needy Disabled (ATD)

   a. A person with a physical or mental di
   which probably will continue for life
   prevents engagement in paid employmen
   homemaker duties.

   b. At least 18 years of age.

5. General Relief (GR)

   a. To meet the needs of people not eligi
   under one of the previous categorical
   programs.

   b. Financed and administered under count
   auspices.

D. Related Agency Program Resources

1. The Food Stamp Program

   The purchase of food stamps at a discount
   increase the food purchasing power and imp
   the nutrition of financially limited perso
   families.

2. Medical Services

   The purchase of selected medical benefits
   persons eligible with a full choice of doc
   and facilities used for such services.

3. State Preschool Program

   A planned child development activity whic
   to prepare disadvantaged children from ec
   ly and/or culturally deprived families fo
   success in the formal educational system.

Discussion of Public Welfare Programs, Services and Resources	Comments, Suggestions
A. <u>Objective</u> To identify and differentiate between the major kinds of social services provided by the agency to clients.	The purpose of this session is to expand the Case Aide's beginning knowledge of agency programs and resources.
B. <u>Some Reasons Why Social Services are Provided</u> 1. To broaden a person's ability to manage his life. 2. To expand each person's range of choices, which he can use in determining his future. 3. To protect people from neglect, abuse or exploitation. 4. To make available additional resources to clients. 5. To help people to utilize agency and community resources more fully in the solution of their problems. 6. To help people more clearly express their problems and needs to the agency as well as other community resources.	Participants should be encouraged to draw upon their wealth of prior experience in identifying why services are provided to clients. The specific reasons listed here are only some of the more often suggested ones - Case Aides will think of many additional ones. Specific examples of each should be offered in illustration of the reasons and purposes for providing social services.
C. <u>Specific Programs, Services and Resources</u> 1. Required Services: a. Information and Referral Services b. Protective Services (1) for adults (2) for children	Discussion can be stimulated by asking participants to identify the kinds of services they have received or know of other persons receiving.

Health Care Services h. Family Planning Services i. Homemaker Services - for adults 2. Recommended Service Programs a. Adoption Services b. Licensing Services c. Educational Training Program d. Homemaker Services - for children	In discussion of these agency programs, the following questions should be answered in relation to each: (1) What is the program or service and why is it provided? (2) To whom is it available and under what circumstances? (3) Who provides the service? (4) How is the client and the program or service brought together? (5) What possible role might the Case Aide play in relation to the particular service? This session can be summarized, using the workbook assignment on page 10 as a basis for discussion. Before the session ends, ask participants to complete the workbook assignment on page 13 before the next session, and review how this is to be completed.

7. An Observational Experience

A. Objective

To identify and discuss in detail, how one employee explains and/or interprets the use of an agency res to a client.

B. The Observational Experience to be Planned

The purpose of this experience is to provide each C Aide with an opportunity to observe an experienced employee (preferably a Case Aide) explain and/or interpret the use of an agency resource to a client.

In this observation, the participant will want to se answers to the following questions:

1. What did the client want or need to know?

2. How was the subject of the resource introduced i the interview?

3. How was the resource explained?

7. An Observational Experience

Comments, Suggestions

Objective

To identify and discuss in detail, how one employee explains and/or interprets the use of an agency resource to a client.

The Observational Experience to be Planned

The purpose of this experience is to provide each Case Aide with an opportunity to observe an experienced employee (preferably a Case Aide) explain and/or interpret the use of an agency resource to a client.

In this observation, the participant will want to seek answers to the following questions:

1. What did the client want or need to know?

2. How was the subject of the resource introduced in the interview?

3. How was the resource explained?

Ask participants to answer the questions on page 12 of their workbook following their observational experience.

A discussion of these experiences should be planned immediately following the observation, which focuses upon answering these questions.

Ask participants to complete their workbook assignment which begins on page 13, in preparation for their next session.

8. The Qualities of a Helping Person

15443

	Comments, Suggestions
f. His questions are answered frankly or, if the answer is not known, he is referred to someone who can answer the question (or the Case Aide attempts to obtain the information for him).	
C. <u>An Exercise in Helping</u> 1. Situation: A Case Aide has been asked to visit with Mrs. Smith, an ADC recipient, who has asked for help in learning to purchase food more wisely on her budget. 2. Situation: Mr. Jones, an OAA recipient, lives in a very isolated part of the county and has increasingly had difficulty purchasing his food and other essentials when his check arrives. The Case Aide has been asked to visit Mr. Jones to determine whether he has been able to acquire these essentials for the month.	Assign one person to the role of "Case Aide" and ask that he respond as he would on the job. A second person is to be assigned the role of "client" and follows the situation described. Divide the remaining group in half. Ask one group to observe the client and the other the Case Aide. After about five minutes of role playing, ask the "Case Aide" and "client" each how he feels he did. General discussion can follow around what each observer saw.
D. <u>The Importance of Understanding Others</u>: 1. Each person is unique. He has his own values, strengths, weaknesses, attitudes, etc. 2. Emotional needs are as important as physical needs. 3. It is important to be interested in the "whole" client. If a mother is concerned about a child's health problem, rather than purpose of your visit, listen to her concerns before proceeding with the purpose of your visit. 4. Differences in the way a person responds may be the result of different perception (one's awareness of the outside world).	Discussion can begin with a review of the workbook assignment on pages 13 and 14. How each participant would respond to the situations can reflect the points here to be taught, and serve as a basis of identifying why it is important to understand the client.

15443

15444

Remember:

a. No two persons perceive the same thing in the same way.

b. Despite your best of intentions, the client m not perceive you as a helping person.

c. Do not be defensive. Instead, attempt to understand why he responds as he does.

5. Be aware of one's own preconceptions. These are a product of one's own background and experiences.

6. Many clients are noticeably fearful and may be easily upset by problems and difficulties they ar experiencing. Recognize the client's fearfulness

7. Clients may react to a Case Aide differently now that he is a representative of the agency, becaus

   a. They may resent their dependency upon the age

   b. They may resent having to live on a less than adequate income.

   c. They may be fearful that they will not conti to be eligible for financial assistance.

   d. Past contacts with the agency may not always have been positive or helpful, from the clie point of view.

   e. They may have felt that they were discrimina against by this or some other agency or institution.

8. The Qualities of a Helping Person

Comments, Suggestions

Remember:

a. No two persons perceive the same thing in the same way.

b. Despite your best of intentions, the client may not perceive you as a helping person.

c. Do not be defensive. Instead, attempt to understand why he responds as he does.

5. Be aware of one's own preconceptions. These are a product of one's own background and experiences.

6. Many clients are noticeably fearful and may be easily upset by problems and difficulties they are experiencing. Recognize the client's fearfulness.

7. Clients may react to a Case Aide differently now that he is a representative of the agency, because:

a. They may resent their dependency upon the agency.

b. They may resent having to live on a less than adequate income.

c. They may be fearful that they will not continue to be eligible for financial assistance.

d. Past contacts with the agency may not always have been positive or helpful, from the client's point of view.

e. They may have felt that they were discriminated against by this or some other agency or institution.

C. Ways of Establishing Rapport

1. Introduce yourself and state the reason for your visit.
2. Express a desire to assist the client.
3. Observe the client for indications of acceptance or rejection. If rejection, try to discover his reasons for not wanting your help. If acceptance, pursue the interview.
4. Informal conversation can help to put the client at ease.
5. Show interest in the client's problems as he sees them.

Comments, Suggestions

Discussion can begin with a review of the assignment completed in the workbook on page 16. From a discussion of whether they agree or disagree with these statements, the characteristic ways of working, for a Case Aide, can be developed. It should be recognized that while these questions may be beyond the capacity of the learner, and that in reality they cannot always be answered easily, they are intended only for use in stimulating discussion.

Ask participants to practice on each other. This can be done by having one person assume the role of "Case Aide" and another the role of "client." The Case Aide can be given the assignment of introducing himself and putting the client at ease. Group discussion can follow in which these factors are identified and listed on a blackboard.

6. Clarify your role in assisting him and enco to seek the help of his Social Service Work Eligibility Worker with problems appropriat areas of responsibility.

C. How to Prepare for a Visit

1. Why are you going to see the client?

2. What is to be accomplished?

3. Telephone or write a letter to the client t schedule the appointment.

4. Gather the information and materials you wi for the interview - forms, list of question pencils, etc.

5. Be as prompt as possible for your interview

D. Some Useful Hints in Talking With Clients

1. Introduce yourself and greet the client by (Names are important).

2. Encourage the client to talk freely.

3. Listen to all that he says.

4. Be sure that you speak so the person can he and use words he will understand.

5. Determine how fast the client can discuss t with you and adjust your speed accordingly.

6. Observe nonverbal communication. (The clien reactions, expressions, concentration on t conversations, etc.)

Comments, Suggestions

7. Pause from time to time so that the person can comment or ask questions. Be sure that he understands what you have said so far.

8. Encourage a relaxed, informal atmosphere in your interview.

9. Notice if the client becomes tired in the interview (this may mean you should continue sometime later.)

10. Make sure that the client is comfortable. This may or may not require privacy.

11. When possible, place sensitive questions nearer the end, rather than the beginning of the interview.

E. Ending Your Conversation

1. Summarize what you and the client have discussed.

2. Review what you and what the client are going to do as a result of the interview (if appropriate).

3. If a follow-up interview is planned, schedule a time for your return.

4. Thank the person for his time.

F. After You Have Seen the Client

1. Jot down notes of what you discussed with the client (particularly important to remember is factual information and details that can be easily forgotten).

2. Ask yourself some questions.

a. Did the interview achieve its purpose? If not, why not?

b. What did I learn about the client that I did not previously know?

c. How did I help? How did the client respond to my help?

d. If a return visit is planned, what will be its purpose?

e. What information did I obtain that would help the Social Service Worker and Eligibility Worker in their work with this client?

f. What questions do I have as a result of this interview?

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: VII. VOLTAGE REGULATOR

PERFORMANCE OBJECTIVE NO.: 7 TITLE: Remove, Replace, and Test Voltage Regulator

CONDITIONS:

This project is to performed on a complete automobile.

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective covers on front seat of automobile
2. Move automobile into proper work station
3. Select proper manual and turn to appropiate chapter
4. Select proper tools and materials
5. Raise hood
6. Place protective covers on fenders
7. Disconnect battery ground cable
8. Disconnect wires from voltage regulator following steps as outlined in manual
9. Remove screws which attach regulator to engine compartment
10. Remove voltage regulator from engine compartment
11. Make all checks and tests as outlined in manual
12. If all checks and tests are satisfactory, place regulator in original position in engine compartment
13. Attach regulator to engine compartment with screws

PERFORMANCE CRITERIA:

9. How Does A Case Aide Help?	Comments, Suggestions
b. What did I learn about the client that I did not previously know?	
c. How did I help? How did the client respond to my help?	
d. If a return visit is planned, what will be its purpose?	
e. What information did I obtain that would help the Social Service Worker and Eligibility Worker in their work with this client?	
f. What questions do I have as a result of this interview?	

A. Objective

To identify and describe how a specific servic provided to a client.

B. Suggested Guidelines for the Experience

The purpose of this observational experience i vide each learner with the opportunity to obse experienced Case Aide in providing a specific, service to a client. The specific service sho selected because it will involve the aide's us interviewing skills as well as doing skills.

The learner should be asked to answer the foll questions:

1. Did the interview achieve its purpose? If not?

2. What did you learn about the client that y previously know?

3. If a return visit is planned, what will be purpose?

4. What information did you obtain that would Social Service Worker and/or Eligibility W in their work with this client.

5. What questions do you have as a result of interview.

Prior to this observational experience it is that the Case Aide who is being observed, shal information she has about this family and the of this contact.

10. Observational Experience	Comments, Suggestions
A. <u>Objective</u> To identify and describe how a specific service is provided to a client.	Ask the Case Aides to complete their workbook assignment on page 18, following this observational experience. The questions they will be answering should be reviewed, to assure that they are understood.
B. <u>Suggested Guidelines for the Experience</u> The purpose of this observational experience is to provide each learner with the opportunity to observe an experienced Case Aide in providing a specific, concrete service to a client. The specific service should be selected because it will involve the aide's use of interviewing skills as well as doing skills. The learner should be asked to answer the following questions: 1. Did the interview achieve its purpose? If not, why not? 2. What did you learn about the client that you did not previously know? 3. If a return visit is planned, what will be its purpose? 4. What information did you obtain that would help the Social Service Worker and/or Eligibility Worker in their work with this client. 5. What questions do you have as a result of this interview. Prior to this observational experience it is important that the Case Aide who is being observed, share what information she has about this family and the purpose of this contact.	A group discussion should be planned immediately following the observational experience to discuss individual reactions and their answers to these questions.

the client is in need of their expertis

15459

II. The Public Welfare Team	Comments, Suggestions
A. <u>Objective</u> To identify the characteristics of a public welfare team and discuss its purpose and function in work with clients.	The concept of a "team" will not be a new concept for Case Aides. From discussion of their own ideas of what a "team" is, these characteristics can be identified and listed on a blackboard.
B. <u>Definition</u> A public welfare team is a group of agency employees who are functionally significant to the provision of social services and financial assistance to a group of clients for which they are jointly responsible.	
C. <u>The Characteristics of a Public Welfare Team</u> 1. They share responsibility for making the agency program relevant to the needs of specific clients. 2. They are the primary group in the agency which can be responsive to him. 3. They share commonly defined goals with each client with whom they jointly work. 4. They are the agency in action for the client. 5. The team comprises a group of specialists - each with expertise in his own right that can be brought into action in solution of client problems.	
D. <u>The Composition of the Team</u> 1. The team comprises each agency employee who has direct contact with the client. 2. Any team member may involve other members whenever the client is in need of their expertise.	Ask participants to turn to page 19 of their workbook, for discussion of team members.

3. The team members and their role.

   a. The Social Service Worker.

   b. The Eligibility Worker.

   c. The Case Aide.

   d. The Volunteer.

   e. The Receptionist.

   f. The Homemaker.

15461

Comments, Suggestions

3. The team members and their role.

   a. The Social Service Worker.

   b. The Eligibility Worker.

   c. The Case Aide.

   d. The Volunteer.

   e. The Receptionist.

   f. The Homemaker.

Define the major functions and tasks performed by each team member.

This diagram lends itself to emphasizing:

1. The client as the central focus of agency concern.

2. The orchestrational role of the Social Service Worker and Eligibility Worker.

3. The mutuality of effort needed to maximize the benefits of agency services for the client.

D. A Team Approach Requires:

1. That the Social Service Worker, the El
Worker, the Case Aide and other team m
the same goal.

2. That they communicate well with each o
between agency teams.

3. That they understand each other's cont
resources.

4. That they collaborate in the solutions
problems related to the job to be done

5. That the various team members assume r
with the client in implementing a goal
service plan.

6. That all team members demonstrate an a
the client as a person of value and wo

7. That each team member have a clear und
of his own role and its limitations.

Comments, Suggestions

D. A Team Approach Requires:

1. That the Social Service Worker, the Eligibility Worker, the Case Aide and other team members share the same goal.

2. That they communicate well with each other and between agency teams.

3. That they understand each other's contributions and resources.

4. That they collaborate in the solutions of daily problems related to the job to be done.

5. That the various team members assume responsibility with the client in implementing a goal-directed service plan.

6. That all team members demonstrate an acceptance of the client as a person of value and worth.

7. That each team member have a clear understanding of his own role and its limitations.

12. Case Presentation and Discussion

A. Objective

To differentiate between the roles and tasks perf by various agency employees working with a speci client.

B. Suggested Guidelines for Case Presentation

A joint case presentation should be planned, invo an Eligibility Worker, Social Service Worker and pertinent staff who have had contact with a spec client (Case Aide, Homemaker, Volunteer, etc.). Social Service Worker can be assigned responsibi leader-coordinator and present information on:

1. Family history, including the length of time family has been known to the agency.

2. The genesis of the problem(s) and the need f financial assistance and social services.

3. The timing and involvement of the various st members who have worked with the family.

4. The overall case plan for services.

Each member of the team will then describe his r activities in relation to the family, including:

1. How they became acquainted with the family.

2. Their role as a team member and the activiti have performed in relation to this client.

3. How these activities have contributed to the plan.

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: VII. VOLTAGE REGULATOR

PERFORMANCE OBJECTIVE NO.: 7 TITLE: Remove, Replace, and Test Voltage Regulator

CONDITIONS:

BEHAVIOR:

14. Connect wires to regulator
15. Connect battery ground cable
16. Start engine and make all checks and tests as outlined in the manual
17. If all checks and tests are satisfactory, return tools, and materials to proper place
18. Remove covers from fenders and store in proper place
19. Close hood
20. Return automobile to proper parking area
21. Remove seat covers and store in proper place
22. Clean work station for next project

PERFORMANCE CRITERIA:

To be able to satisfactorily remove, replace, and test voltage regulator in 1 hour.

Learning time: 2 hours

12. Case Presentation and Discussion	Comments, Suggestions
<u>Objective</u> To differentiate between the roles and tasks performed by various agency employees working with a specific client. <u>Suggested Guidelines for Case Presentation</u> A joint case presentation should be planned, involving an Eligibility Worker, Social Service Worker and other pertinent staff who have had contact with a specific client (Case Aide, Homemaker, Volunteer, etc.). The Social Service Worker can be assigned responsibility as leader-coordinator and present information on: 1. Family history, including the length of time this family has been known to the agency. 2. The genesis of the problem(s) and the need for agency financial assistance and social services. 3. The timing and involvement of the various staff members who have worked with the family. 4. The overall case plan for services. Each member of the team will then describe his role and activities in relation to the family, including: 1. How they became acquainted with the family. 2. Their role as a team member and the activities they have performed in relation to this client. 3. How these activities have contributed to the case plan.	The persons presenting the case should be selected because of their ability to work together and because they are representative of the qualities earlier identified as being characteristic of a "team." Participants should be asked to answer the questions listed on page 21 of their workbook. Question and discussion should be encouraged.

15467

13. Observational Experience

Comments, Suggestions

A. Objective

To compare and contrast the way another public welfare team member works with clients from the way a Case Aide will work with clients.

B. Suggested Guidelines For Planning The Observational Experience

The purpose of this planned experience is to provide each Case Aide with the opportunity to expand his understanding of the roles of other members of the "Public Welfare Team" through observation of another team member. In planning this experience, care must be taken to select someone whose work examplifies the differences in ways of working, from those of a Case Aide, although a relationship to Case Aide functions should be identifiable. Ideally, the observational experience will be of someone with whom the aide will later be working.

Ask the participants to complete the workbook assignment on page 22.

The Case Aide should be given sufficient information about the client to understand the purpose of the interview and why the contact is planned.

Specific areas to be observed include:

1. What does the specific employee do in the interview?
2. How does this differ from what I will be doing?
3. Were any possible Case Aide functions identified as being needed by the client?
4. How can a Case Aide support what this employee is trying to do with the client?

A group discussion should be planned immediately following the experience(s) to discuss these questions.

Comments, Suggestions

e. Between this agency - another social welfare agency and/or institution.

f. Within training group sessions.

4. The Case Aide must treat all information that comes to him while performing his duties as confidential between himself and his trainer/supervisor.

a. What information he is to share with the Eligibility Worker.

b. What information he is to share with the Social Service Worker?

5. Careless divulging of information may seriously affect the relationship between the client and the agency.

The ramifications of confidentiality might be pertinent here.

C. Respect for a Person's Worth

The participants should be asked for personal examples where they believe a helping person expressed or did not express such an attitude towards them.

1. Every individual has human dignity.

2. Respect is the basic element of a helping relationship.

3. One must respect self in order to respect others.

4. The rights of each agency client

a. To apply for public assistance and/or social services.

b. To be given financial assistance, if he is eligible, promptly and without discrimination.

c. To be advised of why the agency may take specific action.

d. To spend the financial assistance he rece the way he wishes.

e. To have information regarding rules and pr of the agency which may affect him or his

f. To agency time, to question facts and cont actions, and to discuss these.

5. The responsibility of the Case Aide to respec client he may meet and work with.

D. Responsibilities of the Client

1. With each right he must assume a responsibili

2. The Case Aide's role in helping a client fulf responsibilities.

a. As an agent, representing the total agenc

b. As a member of an agency team.

c. As a helping person to the client.

d. The client's right to appeal.

"The Principle of Client Self-Determination." Biestek, Felix P., S.J., Social Casework, November 1951.

E. The Client's Right of Self-Determination

1. To determine his own destiny.

2. To accept or reject agency help.

3. To participate in shaping his own destiny.

4. To success or failure.

5. To plan his life on the basis of sufficient i tion being available to him.

15473

Comments, Suggestions

c. To be advised of why the agency may take a specific action.

d. To spend the financial assistance he receives in the way he wishes.

These rights might be listed on one side of a blackboard and their comparable responsibility listed when material in the following section is discussed.

e. To have information regarding rules and procedures of the agency which may affect him or his family.

f. To agency time, to question facts and contemplate actions, and to discuss these.

5. The responsibility of the Case Aide to respect each client he may meet and work with.

D. Responsibilities of the Client

1. With each right he must assume a responsibility.

2. The Case Aide's role in helping a client fulfill his responsibilities.

The positives of helping the client fulfill responsibilities should be stressed.

a. As an agent, representing the total agency.

b. As a member of an agency team.

c. As a helping person to the client.

d. The client's right to appeal.

See examples on page 44 which deal with these issues.

Self- E. The Client's Right of Self-Determination

A question to stimulate group discussion might be:

"How will this influence the ways in which you work with clients?"

1. To determine his own destiny.

2. To accept or reject agency help.

3. To participate in shaping his own destiny.

4. To success or failure.

5. To plan his life on the basis of sufficient information being available to him.

17. A Meeting With Individual Supervisors	Comments, Suggestions
In terminating this first week of orientation, this last two-hour period should be left free for a meeting of participants with their line supervisor. The purpose of this meeting is to lessen anxiety of opportunity for them to become acquainted with their line supervisor, to learn the location of their desk, to meet people with whom they will be working and/ perhaps, to learn any specific rules or procedures to be followed in the specific unit to which they are attached. When the participants leave work, they should clearly know where they are to report on the following Monday and, possibly, what their beginning work assignment will be.	This session might be planned to start as a brief group meeting followed by individual conferences, or the total time can be spent individually with their line supervisor.

pose of Induction Training

pose of induction training is to provide the new Case Aide with sufficient knowledge and beginning to performing those tasks assigned to this classification of staff. As such, this training will pon helping the Case Aide to develop and expand his natural skills and ways of helping people, than to teach him a new or different way of helping clients. The content of the induction training s contained in this training aid have been developed from the more common tasks which have been d to Case Aides in county public welfare departments, and represents the beginning content which taff members will need to perform these tasks. Four broad areas are covered, including:

Specific techniques and aids in performing their job assignment.
The methods used by Case Aides in helping clients.
Additional knowledge about the agency and its clients.
Knowledge needed in performing specific helping tasks.

unty welfare department will want to add additional content areas to the induction training of des, related to the specific tasks assigned to these new employees which have not been anticipated training aid. Specific sessions have been left open for this purpose.

ine of Induction Training Sessions

1 - USING THE TELEPHONE EFFECTIVELY - 2 hours

Principles of effective telephone usage are introduced and an opportunity to practice the use of these principles, within the group is provided.

2 - SOME THINGS TO HELP YOU IN YOUR WORK - 2 hours

This session offers specific help with the mechanics of the job performed by the Case Aide, including keeping a log of their work and writing.

3 - A FRAMEWORK FOR HELPING - 2 hours

This session introduces one approach to work with clients, used by Case Aides, and examines the steps involved in such an approach. The concept of "self-help" is also introduced and techniques used to support this concept are discussed.

Session 4 - HELPING AS A CASE AIDE - 2 hours

This session focuses upon the major aims of Case Aid
the four major ways in which a Case Aide helps clien
and concrete assistance; (2) acting as a model-teach
actions; and (4) providing information about and hel
resources.

Session 5 - UNDERSTANDING AND TALKING WITH CLIENTS - 2 hours

Factors which influence the way in which people comm
the various types of communication and some of the b
self-understanding in order to help other persons is

Session 6 -- COMMUNITY RESOURCES - 2 hours

Major groupings of community resources are presented
ing and discussing specific community resources avai
upon the various needs which these resources are des
for these services.

Session 7 -- HELPING A CLIENT TO USE A RESOURCE - 2 hours

This session focuses upon the various ways in which a
resource together; factors which the Case Aide will w
resource; and discussion of the various steps to be t
and use a community resource.

Session 8 - PLANNED VISITS TO COMMUNITY RESOURCES - 4 to 8 hours
available to clients within the county.)

Planned visits to community resources used by clients
direct knowledge about each such resource, in prepara
in work with clients.

Session 9 - POVERTY: ITS CAUSES AND EFFECTS - 2 hours

Consideration of the nature of poverty, its character
Case Aide in his work with clients, is offered in bro
be viewed.

LPING AS A CASE AIDE - 2 hours

is session focuses upon the major aims of Case Aide activities, the helping process and e four major ways in which a Case Aide helps clients, including: (1) providing material d concrete assistance; (2) acting as a model-teacher; (3) supporting positive client tions; and (4) providing information about and helping the client to use available sources.

DERSTANDING AND TALKING WITH CLIENTS - 2 hours

ctors which influence the way in which people communicate provide a basis for considering e various types of communication and some of the basic needs of people. The need for lf-understanding in order to help other persons is stressed in this session.

MMUNITY RESOURCES - 2 hours

jor groupings of community resources are presented and serve as a framework for identify- g and discussing specific community resources available to clients. Emphasis is placed on the various needs which these resources are designed to meet, and who is eligible r these services.

LPING A CLIENT TO USE A RESOURCE - 2 hours

is session focuses upon the various ways in which a Case Aide might bring a client and source together; factors which the Case Aide will want to consider in selecting a source; and discussion of the various steps to be taken in helping a client to get to d use a community resource.

ANNED VISITS TO COMMUNITY RESOURCES - 4 to 8 hours (depending upon the resources ailable to clients within the county.)

anned visits to community resources used by clients will provide the Case Aide with rect knowledge about each such resource, in preparation for his later use of these work with clients.

VERTY: ITS CAUSES AND EFFECTS - 2 hours

nsideration of the nature of poverty, its characteristics and its implications for the se Aide in his work with clients, is offered in broadening the way in which poverty may viewed.

Session 10 - SOME MYTHS ABOUT PUBLIC WELFARE AND ITS CLIENTS - 2 hou

Some common myths about public welfare and its clients
common misunderstandings about the agency and to handle
attitudes of individual members.

Session 11 - NUTRITION - 2 hours

An introduction to the principles of nutrition and the
comprise the elements of a balanced diet is provided an
of the factors which influence and affect what and how

ne common myths about public welfare and its clients provide a means by which to clarify mmon misunderstandings about the agency and to handle, in the learning group, non-helping titudes of individual members.

TRITION - 2 hours

introduction to the principles of nutrition and the various groupings of food which nprise the elements of a balanced diet is provided and serves as a basis for discussion the factors which influence and affect what and how much a person eats.

AL PLANNING AND BUYING - 2 hours

s session focuses upon the factors which influence meal planning, and suggests one thod for planning and buying food. Through discussion, other methods, used by Case les, can be identified to maximize their use with a variety of clients.

SEHOLD MANAGEMENT - 2 hours

approach to household management is presented and serves as a basis for group discus-n in which participants can share their own ideas and their specific examples can be eralized for wider use with a variety of clients.

ILY BUDGETING - 2 hours

approach to family budgeting is offered in helping participants to identify and discuss skills which they have already developed in managing on a limited budget.

E PRINCIPLES OF CHILD CARE AND CHILD REARING - 2 hours

e principles of child care are presented and the group is asked to identify major racteristics or tasks to be accomplished by a child at various stages in his development. se principles are then discussed in relation to their use in work with clients.

Session 16 - AN EXERCISE IN TEAMWORK - 2 hours

An exercise in teamwork is planned to reinforce th
delivery of social services to clients.

Session 17 through 22 - SUGGESTIONS FOR CONTENT IN SIX SESSIONS -

Suggestions of a number of content areas are offer
can select and plan the remaining six sessions.

Session 23 - REVIEW AND EVALUATION OF INDUCTION TRAINING - 2 ho

A review of induction training sessions, the conte
identified, serve as a summary of training to date
evaluation of these learning experiences.

AN EXERCISE IN TEAMWORK - 2 hours

An exercise in teamwork is planned to reinforce the concept of a team approach in the delivery of social services to clients.

ugh 22 - SUGGESTIONS FOR CONTENT IN SIX SESSIONS - 12 hours

Suggestions of a number of content areas are offered, from which county welfare departments can select and plan the remaining six sessions.

REVIEW AND EVALUATION OF INDUCTION TRAINING - 2 hours

A review of induction training sessions, the content areas covered and major principles identified, serve as a summary of training to date and a basis for group and individual evaluation of these learning experiences.

PERFORMANCE OBJECTIVE STATEMENT

SCHOOL: PETERSBURG FEDERAL REFORMATORY

CURRICULUM: VOCATIONAL

CLUSTER: AUTOMOTIVE

PROGRAM: AUTOMOBILE MECHANICS

MODULE: IV. ELECTRICAL SYSTEM

MILESTONE: VIII. LIGHTING - HEAD LAMPS

PERFORMANCE OBJECTIVE NO.: 8 TITLE: Remove, Replace, Test, and Adjust Head Lamp Assembly

CONDITIONS:

This assignment is to be performed on a complete automobile.

BEHAVIOR:

After satisfactory completion of all related training, proceed as follows:

1. Place protective covers on front seat of automobile
2. Move automobile into proper work station
3. Select proper manual and turn to appropiate chapter
4. Select proper tools and materials
5. Remove right and left head lamp rim following steps as outlined in manual
6. Remove each head lamp retainer ring being careful not to drop head lamp
7. Unplug wires from head lamp and remove head lamp bulb
8. Repeat step #6 and #7 on each head lamp
9. Make checks and tests as outlined in the manual
10. Plug head lamp bulb to wires following steps as outlined in manual
11. Replace head lamp retainer ring
12. Repeat steps #10 and #11 for each head lamp

PERFORMANCE CRITERIA:

References

The customer service department of your local telephone company has a number of useful teaching aids, and may be willing to provide a trainer to cover this content area. They can also vide you with a number of brochures and publications that can be used by trainees.

I. Using The Telephone Effectively

A. Objective

To identify and discuss at least three principles proper telephone usage.

B. What do you do when the telephone rings?

1. First impressions are lasting impressions.

2. A prompt and courteous handling of telephone creates a helping environment for agency work

3. When a caller has to wait on the line through rings he is apt to be annoyed. Always answer phone promptly

   a. A situation to consider:

      You are working with some materials acros room when the telephone rings. The phone several times before you can answer. You the telephone and say what?

   b. A response for the situation:

      "Mr. Smith speaking. I'm sorry to have k waiting; I was not at my desk when the ph began to ring."

4. Use please and thank you liberally in your co sation - this helps to make a good impression

5. Always identify yourself when answering the phone.

I. Using The Telephone Effectively

	Comments, Suggestions
A. <u>Objective</u> To identify and discuss at least three principles of proper telephone usage.	
B. <u>What do you do when the telephone rings?</u>	
1. First impressions are lasting impressions.	This session can begin with a review and discussion of the exercise on page 31 of the workbook.
2. A prompt and courteous handling of telephone calls creates a helping environment for agency work.	
3. When a caller has to wait on the line through several rings he is apt to be annoyed. <u>Always answer the phone promptly</u>	
a. A situation to consider:	
You are working with some materials across a room when the telephone rings. The phone rings several times before you can answer. You answer the telephone and say what?	Ask the group to offer possible responses and select the one which seems the best response.
b. A response for the situation:	
"Mr. Smith speaking. I'm sorry to have kept you waiting; I was not at my desk when the phone began to ring."	
4. Use please and thank you liberally in your conversation - this helps to make a good impression.	
5. Always identify yourself when answering the telephone.	

C. Talking on the telephone

1. Don't talk too fast or too slowly. Adjust your speed to the pace set by the person you are talking with.

2. Be careful not to speak in a monotone. Use the many inflections of which your voice is capable.

   a. A situation to consider:

      "Mr. Smith, I'm so glad you called."

   b. It should sound better when "Mr. Smith" and "so" are emphasized (or "Mr. Smith" and "glad").

3. Speak in a normal conversational tone. Don't shout or let your voice drop to low.

4. Pronounce your words clearly.

D. What to say and what not to say

1. Maintain a focus on the purpose of the telephone call.

2. Answer the caller's questions.

3. Volunteer any information he may need.

4. Listen carefully to what he has to say.

5. Maintain conciseness and politeness, but don't be so brief as to sound discourteous.

1. Using The Telephone Effectively	Comments, Suggestions
<u>Talking on the telephone</u>	
1. Don't talk too fast or too slowly. Adjust your speed to the pace set by the person you are talking with.	
2. Be careful not to speak in a monotone. Use the many inflections of which your voice is capable.	
a. A situation to consider:	Ask the members of the group to try different voice inflections.
"Mr. Smith, I'm so glad you called."	
b. It should sound better when "Mr. Smith" and "so" are emphasized (or "Mr. Smith" and "glad").	
3. Speak in a normal conversational tone. Don't shout or let your voice drop to low.	
4. Pronounce your words clearly.	
<u>What to say and what not to say</u>	
1. Maintain a focus on the purpose of the telephone call.	You may want to discuss the two examples contained in the workbook on page 31, at this point. Which conversation is the most effective and why?
2. Answer the caller's questions.	
3. Volunteer any information he may need.	
4. Listen carefully to what he has to say.	
5. Maintain conciseness and politeness, but don't be so brief as to sound discourteous.

E. When taking telephone calls for someone else

1. Find out who is calling

You might say: (1) May I tell Mr. Jones w calling, please?

(2) Mr. Jones would like t who is calling.

(3) Could you tell me who ing, please, so that I announce your call to

2. If you are screening telephone calls, you m to find out what the person wants.

You might say: (1) Perhaps I can help you

(2) May I tell Mr. Jones w calling about, perhaps be able to help.

F. Some do's and don'ts:

1. If you are taking a message, jot down the m important words - then complete writing the as soon as you hang up the telephone.

2. Don't start anyone on a wild goose chase. are not sure who should handle the call, dor transfer it. Instead, offer to call the per and then find out who has the information he

3. If you get someone who has been traveling fr extension to the next, do not transfer the c again, even if you know who would have the i tion. This person may not be at their desk: offer to have that person telephone them bac

4. Remember to return telephone calls, respond messages, and follow through.

3. A Framework For Helping

A. Objective

To identify and discuss the steps which are usually taken by a case aide in helping clients.

B. Introduction

In order to help a person, the Case Aide must know and understand the client, including:

1. Who the client is.
2. The kind of problems with which the Case Aide may be helping.
3. The resources available for use in the solution of the problem.
4. What the Case Aide will do with the client and how they will, together, seek a solution to the problem.
5. Evaluate the outcome of this helping activity with his supervisor.

C. The Case Aide enables the client to accept and benefit from help through the mutual trust and respect that each develop for the other.

D. The framework:

1. Identifying the problem:

   a. Who is your client? Who are his family? Where does he live and under what circumstances?

3. A Framework For Helping

	Comments, Suggestions
A. <u>Objective</u> To identify and discuss the steps which are usually taken by a case aide in helping clients.
